The presence of the constraints that, all other things being equal, would lead to the violation of the Pareto optimality conditions need not in fact preclude the attainment of the first-best optimum. In some instances the government may be able to neutralize fully the effects of the various distortions and externalities embodied in the constraints and thus mimic the first-best equilibrium. A well-known example of this was illustrated in a 1986 study by Paul Romer. In the study he introduced an endogenous growth model, in which private agents ignore the production externality due to aggregate capital and therefore overconsume and underaccumulate capital, relative to what is socially optimal. By appropriately subsidizing the return to capital, the government can induce the agents to adjust their consumption-savings behavior and thus attain the first-best optimal growth rate.
In most cases the policy maker is likely to have insufficient policy instruments to reach the first-best outcome, in which case the resulting equilibrium will be truly second-best. In such a situation a natural question to consider concerns the policy options available to improve social welfare relative to the second-best equilibrium. In the Romer model, for example, it is likely that to attain the first-best growth rate the required subsidy to capital income is too large to be politically feasible. The policy maker may therefore decide to target a more modest growth objective that can be achieved by different combinations of tax rates and subsidies. The policy maker is faced with several second-best choices and thus with ranking the set of alternatives.

As noted, the optimality conditions characterizing the second-best equilibrium are complex and therefore, as a practical matter, may be difficult, if not impossible, to implement. This issue was addressed by Yew-Kwang Ng in Welfare Economics: Introduction and Development of Basic Concepts (1979) when he proposed a “third-best” equilibrium. He suggested that in cases where policy makers have insufficient information to implement the second-best policies, they should seek to correct only the known distortions and leave the optimality conditions in the undistorted markets unchanged at their first-best levels. This is sometimes also referred to as “piecemeal” policy making.

SECOND-BEST VERSUS FIRST-BEST

The issue of second-best versus first-best policy making is pervasive in economics. Early contributions were concentrated in the area of international economics and the debate between free trade versus protection. Subsequently it has played a central role in public economics, where governments face the issue of financing public goods, with the externalities they entail, using various fiscal instruments with their own distortionary effects. It has also been important in the area of applied microeconomics and industrial organization in dealing with issues related to market structure, barriers to entry, and deviations from competitive behavior. Finally, the existence of production externalities is a cornerstone of much of modern economic growth theory, where they have been important in giving the theory of the second best a dynamic dimension.

THIRD WORLD

The term third world was coined by the French economist and demographer Alfred Sauvy to apply to the developing countries that belonged to neither the American nor the Soviet bloc during the cold war. Countries of the “first world” included the United States, its European allies, Canada, Australia, and New Zealand. Countries in the “second world” referred to the Soviet Union and its East European allies. The third world comprised the rest of the countries.

DEFINITIONS

From its very inception, the term third world has proven problematic. During the cold war, states such as the Philippines and Cuba, closely aligned to one or the other superpowers, nevertheless were considered third world. Even after the conception of the term broadened to include economic backwardness, poverty, and lack of power, confusion as to its meaning persisted. Included in the third world during the cold war years were states that are among the richest in the world (Saudi Arabia, Kuwait), states whose militaries were larger than those of the North Atlantic Treaty Organization (NATO) powers (Vietnam and Iran), and countries that were major powers in their own right (India). Nevertheless, the term stuck, referring loosely to the countries of Africa, Latin America, and Asia, with Israel, Japan, and China usually omitted.

The third world has always been associated with other groupings of states that share “third world” characteristics. One of the most prominent of these is the non-aligned movement, begun in 1955 by the leaders of...
Egypt, India, and Yugoslavia to advance the interests of countries that sought to avoid entanglement in East-West issues. Another prominent organization was the Group of 77 established in June 1964 to promote the economic demands of poorer countries. The Group of 77, now numbering some 130 countries, is a prominent player in international institutions, particularly the United Nations, where it often clashes with the group of developed states known as the Organization for Economic Co-operation and Development (OECD). While the nations that make up these and other groups overlap with the third world, their focused agendas gave substance to what was otherwise an ambiguous term.

Once the cold war was over, whatever meaning third world had was further eroded. The collapse of the Soviet Union brought about the end of the second world, making the term third world especially difficult to justify. Making matters worse, many saw the term third world as pejorative, which in part explains efforts to use other terms, such as developing countries, the South, and LDC (for least or less developed countries).

Despite all these problems, the use of third world persists. In large measure this is because of the belief that the term is usefully descriptive of a class of countries that share similar characteristics. While not all third world countries manifest these characteristics to the same degree (or at all), enough do to consider retaining the category of third world.

CHARACTERISTICS

The first characteristic of third world countries is that they are relatively young. Unlike countries outside the third world that have evolved over centuries, most third world states were artificially created by others. The great majority of third world states are ex-colonies. Outside powers created states where none had existed. Although the degree to which the newly formed boundaries coincided with the boundaries of indigenous societies varies in the third world (e.g., high in Southeast Asia, low in Africa), in all cases a formal division replaced what had been a flexible demarcation. Because of the arbitrariness of their borders, many third world states began as and remain more artificial constructs than coherent units.

The artificiality of the third world states and their colonial heritage has created a situation in which groups owe allegiance to and act for interests other than the national interest. Policies by colonial powers of “divide and rule” and the destruction of existing political entities made integration and a sense of nationalism all but impossible. Instead of identifying with their states, individuals identify with ethnic, religious, or regional groupings. This narrow seeking of interests perpetuates itself by preventing the formation of a national consciousness.

Rather than transcending the differences among these different groups, the state is often simply the representative of the group that holds power in the capital.

Legitimacy is likely to be weaker for third world leaders than for leaders elsewhere. Many regimes in the third world are narrowly based, came to power through force, and use suppression to remain in power. In part this legitimacy stems from a lack of national identity. When people cannot agree on what constitutes the state, they are unlikely to agree on what constitutes legitimate uses of power within the state. Developing states often lack effective institutions for mediating political disputes, intensifying the internal conflicts that frequently arise. Most third world states are not liberal democracies. Despite the rise of nationalism, meaningful political participation and the acceptance of basic rights, such as freedom of speech and religion, toleration of minority rights, and an independent judiciary, are not found in the majority of third world countries.

The power of the third world states, as in other states, derives from the ability to distribute goods. The state in the third world is distinctive, however, in that it controls a much greater degree of wealth and power than any other group in the society. Gaining control of the state is the only means for the ambitious to meet their needs. Hence a major vulnerability of the state is that it controls a much greater degree of wealth and power than any other group in the society. At the same time those in power will mightily resist attempts at replacement because they do not want to relinquish their only opportunity for wealth and influence and because they fear for their lives.

Third world states are also characterized by economic underdevelopment. It is generally thought that third world countries’ citizens are poor, ill educated, and lack access to quality medical care. The World Bank and the United Nations, which categorize nations as to income and other indicators, confirm this view. The World Bank divides countries into four categories: high income, upper-middle income, lower-middle income, and low income. Third world states make up all the low income states and none of the high income ones, with the exception of oil rich Arab countries. Moreover third world countries tend to rank low on measures of human development, such as literacy, access to education, life expectancy, and infant mortality.

One can categorize third world states by means of their self-identification. If a state considers itself to be a third world country, it is likely to have a set of attitudes and goals that are defined by its “third worldness.” For example, third world states overwhelmingly supported the huge price increases in Organization of Petroleum Exporting Countries (OPEC) oil in 1974 despite the horrendous economic effects they caused. Third world solidarity has also been displayed in votes at the United Nations.
Nations, where countries seen as third world tend to vote similarly. It is possible to speak of a third world therefore because member states do and because they act in at least some ways in terms of their self-identification.

These generalizations are not set forth to suggest that all third world countries share these characteristics equally. Different states manifest different characteristics. Nor do these generalizations apply only to the third world. As demonstrated by the collapse of the second world in 1989, states outside the third world also suffer from problems such as weak legitimacy. What some say justifies considering the third world as a category is that whatever combination of factors may exist in a particular third world state, their cumulative impact makes virtually all third world leaders more vulnerable to overthrow—particularly by internal threats such as coups and rebellions—than other leaders.

Finally, the third world is not a static category. Countries formerly considered to be in the third world have left that status behind, while other states that had been second world countries find themselves increasingly being considered third world. Countries such as Taiwan can become more politically stable, or previously stable countries can plunge into chaos, as occurred with Yugoslavia. Some states, such as South Korea and Singapore, have achieved impressive levels of economic development, while others, such as many of the former Russian republics have descended into “third world” levels of poverty and despair.

There is little question that third world is a messy, ambiguous, and vague term. For those who demand rigor in their definitions, the category of third world has long lost its utility. And yet the persistence of the term indicates that it satisfies a need for many in describing the condition of states and peoples that is not met by any other categorization. As long as poverty and instability exist, so too will the relevance of the category “third world.”

THOMPSON, EDWARD P.
1924–1993
Edward Palmer (“E. P.”) Thompson was an historian and social activist. His first significant publication, William Morris: From Romantic to Revolutionary (1955), was produced under the auspices of the Communist Party Historian’s Group, of which he was an early and active member. Although this is still an enormously important work, Thompson is best remembered for his writings and activities following his resignation/expulsion from the Communist Party (CP) in 1956, which resulted from his criticism of the party’s support for the Soviet invasion of Hungary. Following his departure from the party, Thompson—along with John Saville, with whom he had been publishing The Reasoner (renamed The New Reasoner in 1956), Raymond Williams, Stuart Hall, and others—founded New Left Review in 1960 as one of a number of endeavors to maintain and foster a non-Labour, non-CP left in Britain.

Although generally overshadowed as a theorist by Williams and Hall, Thompson’s polemics on culture, history, and power in this period deserve reexamination for the manner in which they presaged developments in anthropology and literary studies some thirty years later, and his own later understanding of class.

CULTURE
Like Williams and Hall, Thompson found in the concept of culture (both in its anthropological and humanistic senses) an alternative to the economic determinism that dominated Marxist thought. Williams endeavored to expand the traditional capital C Culture to include the contributions of working people, which were often occluded in such discussions, effecting a mutual interpretation of this humanistic culture with its small c anthropological cousin. Thompson railed against Williams’s notion of culture as a “whole way of life” as being innocuous of a “cozy consensus” and not going far enough. Thompson instead argued that culture was more fruitfully viewed as a “whole way of conflict”—not a more or less static, atemporal, and apolitical entity, but itself formed by and generative of social struggle.
Secondly, though both Hall and Williams would retain some form of the basis/superstructure model, Thompson sought to jettison it altogether. Thompson viewed the economic “basis” as the product of social struggle, whereby economic activity had been gradually divorced from all moral and social constraints. To this end, he deployed a generous reading of Marx’s concept of production, arguing that, in effect, the economy was indistinguishable from the human beings who collectively produce a society with economic laws, and “discover,” and are governed by those laws. In this stroke, one glimpses Thompson’s distaste not only for political economy, but also for its left opposite number, “Structural Marxism,” both of which he saw as abdicating morality, agency, and responsibility by theologizing what was itself a human production.

**CLASS**

Thompson brought these understandings fully to bear in his *Making of the English Working Class* (1963) (*MEWC*). Though often confused with the “advocacy” histories that came in its wake (which is not to say Thompson was not an advocate of his subjects), the *MEWC* should not be viewed as a treatment of how class “ought” to look, but a history of how the working class in England came to look as it did on the eve of Chartism. The book ranged across seemingly unconnected domains, from Methodism to the de-skilling of trades to demonstrate both the experience of the working class and its “handling” of these experiences. The emphasis of the book was squarely placed on the concept of *making*, and an argument that class is a relationship and a process, not a “thing” that could be abstracted from its historical context and studied in isolation. Class, he argued, came about over time as a result of struggle, as the realization of mutual and antagonistic interests in human society that come to be articulated in class ways. Because class is an historical process, neither the experience nor the articulation is ever “finished.”

Thompson’s understanding of class endeavored to bring matters down to earth, to demonstrate the role ordinary people have in making their own history—both in terms of his eighteenth-century subjects and as a sort of *ana-amnesis* for the 1960s, with its early rumblings of what would come to be known as *postmodernism*. For Thompson, history had no preordained “direction”; it was quite literally what people (based “on experiences inherited or shared”) made it—that the black hats could (and often did) win out gave a sense of urgency to his subjects and, by extension, to the present. Thompson’s *MEWC* was not a mining of the past for justifications in the present, however; it offered little safe ground for the reader (themselves historical subjects)—because struggle is always (at least) two-sided, and ongoing, each victory remains in jeopardy.

Thompson’s sprawling, impressionistic opus had an enormous and almost immediate impact in historical studies. From a methodological standpoint, the inclusion of literary sources as a form of historical evidence was novel, as were his attention to anonymous letters and (“fumigate[d]”) readings of spy reports. He viewed each in its turn as participating in what he called the “handling” of experience and in so doing managed to reposition politics in terms of the everyday.

Following the publication of *MEWC*, Thompson’s historical output was scant—in addition to a study of William Blake, he produced only two further volumes of historical writing in his lifetime—*Whigs and Hunters* (1975) and *Customs in Common* (1991)—the latter consisting largely of essays that had appeared in various forms over the previous two decades. On this count, the two major essays that followed *MEWC*—“The Moral Economy of the English Crowd in the Eighteenth Century” (1971) and “Time, Work-Discipline, and Industrial Capitalism” (1967) (both collected in *Customs*)—rivaled the importance and influence of *MEWC* and deserve special mention.

Both essays drew on concepts and addressed concerns introduced in *MEWC*. In “Moral Economy,” Thompson demonstrated that far from being spasmodic eruptions of hunger or “collective psychosis” (LeBon), English grain riots exhibited logic and discipline and were an attempt to enforce moral constraints upon the market. Thompson found a customary sense of fairness, a component of plebeian, and to a great extent also patrician, sensibilities being negotiated in the riots. The riots were not opposition to capitalism per se, as the rioters often sold seized grain at what they considered a fair price, giving the money to merchants (occasionally with magistrates looking on), but opposition to a market divorced of all moral and social concerns.

In “Time, Work Discipline, and Industrial Capitalism,” Thompson examined the rationalization of labor and time over the course of the eighteenth century. Drawing on a typically impressive array of local sources, which he linked up to anthropological studies of noncapitalist societies, Thompson demonstrated that time and labor, which had been rooted in the human body and natural processes, were gradually estranged from those processes to conform to notions of abstract labor power and clock time, both of which mirrored the money form. Thompson’s essay, unlike the more celebrated work of Michel Foucault on similar themes, had the merit of moving beyond the truism of power and the tendency of human activity to increase its scope (power + resistance = power’, power’ + resistance = power”, …∞) by gearing
analysis toward concrete forms of domination and their attenuation (also, incidentally through human activity). Put simply, while it may be the case that all roads lead to power, people have to live in a world in which the concrete forms and variable severity of “power” matter very much to them.

This sensibility informed his 1975 *Whigs and Hunters: The Origin of the Black Act*. The book was a microscopic study of the 1723 “Waltham Black Act,” notorious for exploding the number of capital offenses against property in England by criminalizing traditional forms of plebeian subsistence. Though on one hand granting that the new laws represented a transparent power grab on the part of an emergent capitalist class, Thompson steadfastly refused to see the new laws as merely that. Instead, he argued that, though susceptible to ruling class interest, these laws codified a “ground” that also constrained ruling class interests and could be (and later were) used as a check against the arbitrary power of those interests.

While Thompson was perhaps one of the greatest historians of the twentieth century, his historical work was interrupted by periods of intense political activity, for which he is remembered as both a charismatic speaker and a devastating polemicist. Beginning with his exit from the CP, Thompson polemicized—first in *The New Reasoner* and *New Left Review*, and later in a myriad of mainstream newspapers and magazines—on everything from imperialism to the welfare state, but his central concern remained nuclear disarmament. Thompson, whose involvement with the Campaign for Nuclear Disarmament (CND) was early and continued, viewed the atomic bomb, and the polarization it created, as inimical to democratic institutions. He did not view the bomb as a particularly deadly “add on” to “economic man” (capitalist or “communist”), but as economic man’s realization. Thompson envisioned a Pan-European, nuclear-free “third way” (not to be confused with the Blairite vision of the same name) that divested itself both of Soviet and American influence, both of which, he argued, utilized the threat of nuclear war to suppress democratic self-determination the world over. With the arrival of cruise missiles in Britain under Margaret Thatcher, he stopped his historical writing almost entirely, and devoted his energies to Europeans for Nuclear Disarmament (END). He was (to the chagrin of Thatcher, no doubt) the most recognized person in Britain after the Queen in the early 1980s, and both the Soviet Union and United States exerted a great deal of effort in insinuating that he was an “operative” for the other. Nonetheless, END’s success was enormous, rallying huge numbers of both “free” and “Communist” Europeans to its cause. Seldom remarked upon in the United States, the movement exerted enormous pressure, particularly in Eastern Bloc countries, and had what historians are beginning to recognize as a significant role in Soviet disengagement from those countries.

**CRITICISM AND THE “CRISIS OF CLASS”**

Thompson’s privileging of the class “concept” as the defining historical experience began to come under fire in the early 1980s and reached something of a fever pitch following his death in 1993. Joan Scott presented “The Women in the Making of the English Working Class” at the American Historical Association’s session honoring the twentieth anniversary of the publication of *MEWC*. She argued that class as it had been “theorized” by Thompson was a masculine concept, and Thompson had made it more so with his tendency to masculinize “it” by describing his book as a kind of “biography” of the working class from its “youth to early manhood.” She further castigated Thompson’s book for its treatment of the prophetess Joanna Southcott (who, among other things, claimed to be pregnant with the son of God, and whose followers Thompson had described as “deluded”). If Scott’s criticism strikes the reader today as a quaint search for masculine pronouns in the guise of a critique, at the time it was (and it remains) something of a declaration of independence for feminist historians who had had an uneasy relationship with class. Scott’s essay raised the possibility for many that “the class concept” was in fact hostile to feminist ambitions.

Further influential criticisms came from Dipesh Chakrabarty and Linda Colley, the first offering a postcolonial critique of Thompson, and the latter attempting to displace the notion of class with that of *nation*. Chakrabarty questioned the suitability for India of the class concept as “theorized” by Thompson, insisting on the primacy of religious identity there (particularly as opposed to the liberal traditions and institutions of “the Freeborn Englishman”). Colley, for her part, argued, by sidestepping class more or less altogether, that over Thompson’s period, people came to identify themselves as “Britons” above all else.

In Chakrabarty’s case, one questions the depth of engagement with Thompson’s work, particularly given the primacy Thompson accords to such things as Methodism, and his insistence that the identity of “Freeborn Englishman” was not stable either in its application or content—just who this applied to and what it meant was a matter of centuries long contest. In Colley’s criticism, the notions of *patriot*, *Briton*, and so forth tend to be stripped of their contextual specificity: The very Thompsonian questions of who is speaking, in what context, and how they mean what they are saying were generally ignored or overshadowed by the meta-identity of being “British.” Though Thompson allowed in his review
of Colley’s Britons that nationalism was undertheorized and underexplored in his work, he bristled at the book’s tendency to melt all concrete utterances into one nationalist soup.

Though neither Chakrabarty’s nor Colley’s critiques can be viewed as ultimately satisfactory from an intellectual standpoint, both have enjoyed a great deal of institutional success. Colley’s Britons, in particular, has opened the closet door for a historical establishment in Britain that was always hostile to studies of class, if consistently unable to outflank Thompson in debate. Thus, where these historians might have been forced to address the question of class previously, they now proceed as though all were on board with the British ship of state and write “Imperial” history as though the thirty years of MEWC’s primacy had never occurred.

**LEGACY**

Thompson’s legacy is difficult to determine. His self-appointed heirs have often proven sloppy in research, theoretically uninquising, and off-putting in argument. Others who have more closely engaged themselves with the possibilities in Thompson’s work have tended to retreat into the cutting-edge hinterlands of historical study, particularly the *Journal of British Studies*, where the sort of interdisciplinary and theoretical engagement Thompson advocated is better received. Even though interdisciplinary study has flourished in recent years, the tendency has been toward a sort of compartmentalization, and for these very institutional reasons, one finds it difficult to imagine again the sort of all-out assault on received historical paradigms that MEWC represented.

From a political standpoint, one is again scarcely able to conceive of Thompson’s moment. Thompson once wrote of a “peculiar and vengeful kind of bitterness that a certain kind of man feels for an enchanted mistress who has disappointed him” (O’Brien and Vanech 1969), and that hostility to or disenchantment with the possibility of social transformation seems the patrimony of the ’68 generation. Between an academic left as convinced of an omnivorous “power” as it is of human impotence or unwitting complicity in the face of it, and a political left that no longer recognizes, much less is able to converse with working people, Thompson appears something of a relic, ironically the very “damned fool in utopia” he was labeled at his expulsion from the CP. It remains to be seen how long human beings can both go on living and being so “smart.”

Thomas, Keith. 1992. How Britain Made It, reviews of Britons: Forging the Nation, 1707–1837, by Linda Colley, and *The...
THOREAU, HENRY DAVID 1817–1862

Writer, naturalist, theorist of civil disobedience, and anti-slavery activist, Henry David Thoreau was born in Concord, Massachusetts, and lived there most of his life. A graduate of Harvard College, his most formative intellectual experience was his friendship with Ralph Waldo Emerson (1803–1882). The central figure of New England transcendentalism, Emerson famously called on individuals to dispense with traditional religious and intellectual authorities and seek truth and divinity for themselves. Thoreau spent his life answering Emerson’s call to establish “an original relation to the universe” (Emerson 1983, p. 7).

Thoreau’s most concerted effort to connect directly with the universe was his two-year sojourn in the woods at Walden Pond. Thoreau lived in a cabin of his own making, sustained himself by his own labor, looked inward, and observed nature. He recounted his experience magisterially in Walden (1854): “I went to the woods because I wished to live deliberately, to front only the essential facts of life, and see if I could not learn what it had to teach, and not, when I came to die, discover that I had not lived” (Thoreau 2004b, p. 90). Walden urges mental awakening and original perception; it also urges simple living so that one may free oneself from the relentless acquisition of material goods and the unquenchable thirst for riches.

In 1846, Thoreau had a brush with the law that spawned his other great contribution to American letters. Walking through town, he ran into the tax collector, who demanded that he pay his poll tax. Thoreau refused because he did not want his money going to support the Mexican War, which Thoreau saw as an indefensible attempt to extend the reach of American slavery. The tax collector threw Thoreau in jail; the next day an acquaintance paid the tax for Thoreau, much to Thoreau’s irritation. Thoreau’s night in jail became the occasion for “Resistance to Civil Government”—his 1849 essay defending his refusal to pay the tax and arguing that morally unconscionable laws are not binding. Eventually re-titled “Civil Disobedience,” Thoreau’s essay is the foundational text of the modern doctrine of civil disobedience: Citizens may justifiably defy laws which break with higher moral laws or with the moral foundations of the polity. In the twentieth century, Indian leader Mohandas Gandhi and American civil rights leader Martin Luther King Jr. drew inspiration from Thoreau in formulating their respective theories of nonviolent resistance. Unlike Gandhi and King, however, Thoreau was not a committed pacifist.

Thoreau gave three more noteworthy antislavery addresses before his death. In “Slavery in Massachusetts” (1854), Thoreau excoriated the recently passed Fugitive Slave Law, which required free states such as Massachusetts to assist slave-owners in the recovery of their property. In “A Plea for Captain John Brown” (1859) and “The Last Days of John Brown” (1860), Thoreau defended Brown’s failed raid on the federal arsenal at Harpers Ferry, Virginia, which was part of Brown’s broader attempt to incite a slave insurrection throughout the South. Despite his hatred of slavery, the carnage of the Civil War greatly disturbed Thoreau. Falling ill just before its outbreak in 1861, he said he “could never recover while the war lasted” (Harding 1992, p. 451). Thoreau never did, dying of tuberculosis at the age of forty-four.

Jack Turner
THORNDIKE, EDWARD
1874–1949

Although he spent his mature career in educational psychology at Columbia University’s Teachers College in New York City, American psychologist Edward Lee Thorndike’s most important work was done in animal learning, begun at Harvard under William James (1842–1910). Thorndike, along with Russian physiologist Ivan Pavlov (1849–1936), provided the methodological tools of behaviorism, in which psychologists used animal models to formulate theories of learning and behavior that would include humans.

When Thorndike and Pavlov began their research, comparative psychology used the so-called anecdotal method—collecting stories about animal behavior in natural and seminatural settings—in order to understand conscious animal thinking. Thorndike challenged the anecdotal method for lack of control, overestimation of animal intelligence, and tendencies to anthropomorphize the animal mind. He substituted experiments for anecdotes, establishing one of the two major paradigms for studying learning: instrumental, or operant, conditioning. Contemporaneously, Pavlov established Pavlovian, classical, or respondent, conditioning. With regard to animal thought, Thorndike set out to catch the animal mind at work but concluded that animals do not reason their way to problem solutions. Rather, they engage in mindless trial-and-error learning.

In the experiments that defined instrumental conditioning, Thorndike placed young cats inside wooden cages called puzzle boxes from which they could escape by working a manipulandum inside the box, such as a foot treadle. Thorndike observed that cats tried out a variety of instinctive responses before accidentally hitting on the correct response. Nor did they show insight. Instead of stepping on the treadle immediately on the next trial, cats repeated erroneous responses, although the correct response emerged sooner as trials progressed until it became dominant. Thorndike described the process of learning as a gradual “stamping out” of connections between the box stimuli (S) and the incorrect instinctive responses (R), and the gradual “stamping in” of connections between S and the correct R. Hence, Thorndike called his theory of learning connectionism, a behavioral version of associationism.

Thorndike proposed three laws governing learning. The law of exercise held that using a connection strengthened it and disuse weakened it, while the law of readiness stated that when a connection was available, its use would be satisfying to the organism; these laws were later abandoned. Most important was the law of effect. Initially, the law of effect held that when a response to a stimulus led to pleasure, the S-R connection was strengthened, and when a response led to painful punishment, the connection was weakened. Thorndike later revised the law of effect, having found that punishment did not weaken S-R connections, but inhibited their expression, a view held today.

Because Thorndike never proposed a comprehensive system of psychology, his ideas were subjected to detailed rather than systematic criticism. Most significant were critiques of the law of effect and the methodology of the puzzle boxes. Eager to purge references to mental states from psychology, behaviorists objected to Thorndike’s reference to “pleasure”—a subjective conscious feeling—as the cause of learning. They substituted less mentalistic causes such as contiguity of stimulus and response (Edwin R. Guthrie [1886–1959]) or biological drive reduction (Clark Hull [1884–1952]), or they defined reinforcers functionally as events that strengthen the responses that produced them (B. F. Skinner [1904–1990]). Later, as information-processing views of learning gained strength, psychologists questioned Thorndike’s law of effect in a new way (anticipated by Edward C. Tolman [1886–1959] in the 1930s). Thorndike assumed that rewards and punishments work via pleasure and pain, but they also provide information (a concept not available to Thorndike) that a response was correct or incorrect. Experiments that separate the two (e.g., making a painful stimulus indicate that a response was correct) have shown that learning depends on the information value of reinforcers more than their subjective quality.

The Gestalt psychologist Wolfgang Köhler (1887–1967) offered an important criticism of Thorndike’s puzzle-box method. One of the driving issues in psychology of learning is whether learning occurs gradually or can occur suddenly via insight. Thorndike found no signs of insight in his puzzle-box studies, while Köhler found evidence of insight in his studies of problem solving by chimpanzees. Köhler argued that Thorndike’s method was faulty because it made insight impossible: Trapped in the puzzle box, the cat could not see the connection between the manipulandum and the door opening, and so was forced to resort to trial and error. In Köhler’s experiments, on the other hand, all the elements needed to solve a problem were available to the subject, who was able to assemble them insightfully into a solution. The force of Köhler’s critique extends beyond issues of learning. Psychologists perform experiments in order to discover laws explaining behavior in real life, but experiments are necessarily artificial, and may lead psychologists to propose universal laws of behavior that are in fact laws induced by their experiments.

Nevertheless, Thorndike’s influence was enormous. He initiated the S-R concept of learning elaborated by Clark Hull and his followers from the 1930s to the 1960s,
which overshadowed the cognitive tradition of the Gestalt psychologists and Edward Tolman, which held that learning consisted of developing internal representations of the world, the main view in cognitive science today. The law of effect provided the basis for Skinner’s principles of reinforcement, though Skinner did not view operant learning as making connections. There is today a new “connectionist” (neural network) movement, but it is not linkable to Thorndike.

THRESHOLD EFFECTS

According to Eric Naevdal in his 2001 article “Optimal Regulation of Eutrophying Lakes, Fjordes, and Rivers in the Presence of Threshold Effects,” the use of threshold effects is widespread in natural and social sciences alike. A threshold represents a gateway from one description of the world into another, which may be quite different. More precisely a threshold effect describes a process by which the magnitude of the response variable changes significantly as the triggering stimulus exceeds some critical value. One can think of threshold effects as devices to explain nonlinear phenomena.

HOW DO THRESHOLD EFFECTS WORK?

A way of understanding how threshold effects work is by means of an example. In economic growth, one of the main theories developed to explain the process of per-capita income growth in an economy is the one that allows for human capital to affect the production of output overtime. Human capital refers to the stock of knowledge that is accumulated through education and technological progress. These resources make workers more productive and able to adapt to new technologies. Most of the theoretical models that deal with the relationship between human capital and growth assume that this relationship is linear: Increasing the level of human capital should yield a higher rate of economic growth irrespective of the level of human capital, something, according to Pantelis Kalaitzidakis, Theofanis Mamuneas, Andreas Savvides, and Thanasis Stengos in their 2001 study, not borne by empirical evidence.

Costas Azariadis and Alan Drazen observe in their 1990 article “Threshold Externalities in Economic Development” that long-run growth rates exhibit persistent differences between more and less developed economies. Historically this derives from the “Big-Push” ideas of P. Rosenstein-Roden (1943) and Ragnar Nurkse (1953) who have noted that an economy can remain stuck in an underdevelopment state unless there is a substantial investment effort. Some low-income economies appear to be caught in a low-growth environment and lag behind countries similar in terms of endowments. The standard growth model cannot account for such persistent differences. While one can seek explanations for this stylized fact in non-economic factors, there is an economic explanation based on the existence of technological externalities with a threshold property that allows for economies with very similar structures to exhibit different growth experiences. Specifically, once human capital attains a certain threshold level aggregate production possibilities may expand especially rapidly. Economies that have not attained this threshold level may languish in a self-perpetuating state of persistent underdevelopment.

Nonlinearities due to the presence of threshold externalities in the production of human capital can lead to different growth experiences, including possible low-growth (or low-development) “traps,” where low investment in human capital (education) will discourage further human capital accumulation (acquisition of additional skills) and, hence, result in a low-growth trap. Consequently, a group of countries with unequal initial educational endowments may never catch up to each other; the growth rate of ones with higher endowments will diverge from those with lower initial endowments of human capital. This suggests a role of government intervention in the educational sector to introduce policies (such as educational subsidies) that support skill acquisition and higher educational attainment.

NONLINEARITIES AND THRESHOLD EFFECTS

As explained above, threshold effects are the main cause for the presence of nonlinearities in the process that underlies economic growth. From a modeling point of view, threshold effects only produce a specific type of nonlinearity that is quite restrictive. The process that is induced by thresholds can be described by piece-wise linear segments that are individually defined by thresholds. Thresholds act as the “knots” that connect the different segments together. In that case a threshold effect is an “all
or nothing” effect as values below and above the threshold result in different regimes. Alternatively, such regime change could occur gradually and not as abruptly by means of a smooth transition. The amount of smoothing done to the knots that connect the linear segments will result in different types of nonlinear effects. Assuming that smoothing is arbitrary there is a large class of such smooth transition nonlinear effects that includes threshold effects as a special case. Yet despite their limitations, threshold effects have proven to be powerful devices to introduce nonlinearity in economic modeling, especially growth theory.

THURMOND, STROM

1902–2003

Strom Thurmond was born James Strom Thurmond on December 5, 1902, in Edgefield, South Carolina. He was one of six children born to John William Thurmond and Eleanor Gertrude Strom. Thurmond’s father was a lawyer, farmer, community leader, and former South Carolina state senator. Strom followed in his father’s footsteps by acquiring a self-taught law degree (under the tutelage of his father) and entering politics after his 1923 graduation from Clemson College (now Clemson University). In 1928 Thurmond was elected the superintendent of education for Edgefield County. In 1932 he was elected a state senator of Edgefield County. In 1938 he was sworn in as an elected state judge, but he voluntarily gave up his judgeship in 1942 to enlist in the army during World War II (1939–1945). Thurmond became governor of South Carolina in 1946 when he beat the incumbent governor, Ransom J. Williams, (and nine other candidates) in the South Carolina gubernatorial race.

Thurmond was an avid Democratic Party politician, but the 1948 presidential election became a benchmark year for what became his and southern Democratic politicians’ revolt from the national party. Democratic president Harry S. Truman’s 1948 reelection campaign advocated pro–civil rights legislation (abolition of the poll tax, support of an antilynching law, the creation of a permanent Federal Employment Practices Commission, and a ban on discrimination in commerce). Southern states reacted negatively to this platform by revolting from the national party to form their own, pro-segregation and antiblack civil rights, wing of the party—the Dixiecrats, or States’ Rights Party. Thurmond was nominated the Dixiecrat presidential candidate, officially representing the party’s position that states had the right to retain segregation. Thurmond lost the election, but his staunchly southern pro-segregation and antiblack civil rights positions launched him into the helm of southern political leadership.

Thurmond was elected a U.S. senator of South Carolina in 1954, and during his tenure he opposed the passage of several civil rights bills—the Civil Rights Acts of 1957 (in obstructing the bill’s passage he set the record for the longest Senate filibuster—twenty-four hours and eighteen minutes), the Civil Rights Act of 1964, and the Voting Rights Act of 1965, all of which were important in advancing blacks’ civil rights. His continued dissatisfaction with the Democratic Party’s stance on civil rights issues led him to sever his ties with the party in 1964 and become a Republican.

Despite Thurmond’s initial support for Lyndon B. Johnson (a southern Democrat from Texas) as the vice presidential candidate in 1964, Thurmond later openly opposed the national party’s liberal plank on civil rights. The summer before the 1964 presidential election, Thurmond decided not to attend the Democratic national convention because of his ideological differences on civil rights, which separated him from the national party’s politics. In a 1964 speech to a South Carolina audience, Thurmond denounced the Democratic Party platform and announced his realignment with the Republican Party and his support of Barry Goldwater’s (a Republican senator from Arizona) 1964 presidential candidacy. Thurmond found more ideological connections with the conservative Goldwater, who, although he was not a segregationist per se, had outlined in 1961 a “southern strategy” to invite southerners to support the Republican Party as the anticivil rights political party. Thurmond’s partisan realignment influenced the eventual realignment of most white southern Democrats to the Republican Party. His realignment with the Republican Party also laid the foundation for what would become a new and lifelong commitment to this political party.
During much of Thurmond’s political career, his politics were marred with antiblack interests. He was an avid supporter of “freedom of choice” school desegregation plans (despite their being declared unconstitutional by the 1968 Supreme Court case *Green v. New Kent County*), which were a part of the “massive resistance” that southern governments implemented to avoid desegregation. Often, freedom of choice desegregation plans retained former segregation practices—whites who opposed desegregation chose to attend white schools (in order to avoid contact with blacks) and blacks who more than likely supported desegregation continued to attend all-black schools (in order to avoid intimidation by whites in integrated schools).

The issue of freedom of choice plans was at the center of the 1970 South Carolina gubernatorial race, and the candidate who supported the plan (South Carolina congressman Albert Watson) lost to the candidate who opposed it (South Carolina lieutenant governor John West). This political victory attested to the significance of the candidate’s more moderate views on race and his appeal among a majority of black voters. After witnessing this change in how elections could be won in South Carolina politics, Thurmond became more open to considering blacks’ political interests and to broadening his constituent service to South Carolina’s black electorate. He even hired a black staff member, Thomas Moss, who informed him about black political issues.

During the 1970s Thurmond continued to build his relationship with the black electorate, but despite this changed political interest in addressing black issues, Thurmond (as chairman of the Senate Judiciary Committee) initially opposed support of the 1982 Voting Rights Act, which would have extended the provisions of the Voting Rights Act of 1965 that protected blacks’ voting rights. He eventually supported the act.

Over time, Thurmond climbed the political ladder, achieving high political posts such as chairman of the Senate Judiciary Committee and serving as president pro tem (1981–1987; 1995). He was the longest-lived and longest-serving U.S. senator, having reached the age of 100 during his service. At his 100th birthday celebration, Trent Lott (R-MS) made controversial remarks about Thurmond’s 1948 presidential candidacy that eventually led to Lott resigning from his position as senate majority leader. In January 2003 Thurmond retired from his senate position. He died in the same year on June 26, 2003.

Posthumously, rumors about his having fathered an African American daughter resurfaced and were confirmed when Essie Mae Washington-Williams announced that she was, in fact, Thurmond’s daughter. Thurmond’s fathering of an African American daughter (with the Thurmond family African American housekeeper, Carrie Butler) conflicts with a major principle of segregation—the prohibition of “race mixing,” or miscegenation. According to segregationists, blacks and whites are supposed to be divided in every way of life, especially sexual relations, and antimiscegenation laws in the south banned interracial marriage and interracial sexual relations. Thus Thurmond had covertly defied the racial and sexual social mores that he publicly supported. Thurmond was married successively to Jean Crouch and to Nancy Janice Moore (with whom he had four children); both of them were (white) former Miss South Carolinas.

**TIME**

From the perspective of the natural sciences, time in and of itself causes nothing. Being but the interval between the motions of material objects, it is a gauge of change with no natural divisions. Such is not the case for most social...
times, where time has a causative role in shaping action and its perception. Humans mark its passage with ceremony, hope, and anxiety. The approach of a bureaucratic deadline or belief in an impending apocalypse can generate a flurry of culminating behaviors. Time is used as a reward, such as being given “time off” or promoted “ahead of time,” or as punishment, when one “does time” or is placed in “time out” for moral violations. Time, in addition to space, constructs the very boundaries of social reality by ordering social life and shaping individuals’ awareness of its passing.

Born without any temporal instinct or sense, human existence is largely orchestrated by external pacemakers, or Zeitgeber. Upon entry into the world, infants’ first lessons are largely temporal as they come to internalize the rhythms of their families’ language and activity schedules. With maturation, their lives become controlled by the metronomes of school, work, leisure, and community.

The most all-encompassing of these external times come from one’s culture, whose tempos underlie its music, poetry, language, sports, and religion. Cultural systems can be likened to massive musical scores whose rhythms, argues anthropologist Edward T. Hall, “may yet prove to be the most binding of all the forces that hold human beings together” (1983, p. 156). Thus state-of-the-art technologies have historically been applied to time’s measurement: Just as modern peoples measure time by the vibration of atoms, so prehistoric peoples constructed huge monoliths to coordinate social time with cosmological calendars.

The broadest of cultural time conceptions involve orientations toward the future and past. The “Golden Years,” for example, can be collectively understood to exist either in the future (hence, time is seen as progressive and evolutionary) or in some idyllic past (as Paradise lost). The future can be in the past if the flow of time is culturally understood to be recurrent and reversible. A near universal myth holds that the world goes through cycles of destruction and regeneration (Eliade 1949), evident in beliefs about the cyclical nature of both natural and social phenomena. Where time’s flow is understood to be linear and irreversible, the future can be either progressive (i.e., the outlook engendered by the Enlightenment and industrialization) or degenerative (i.e., theologians’ belief in humanity’s growing cultural depravity since the Fall or cosmologists’ predictions of a universe increasingly filled with black holes). These two broad orientations underlie distinction between traditional and modern cultures.

Cultural times are interwoven with social needs, the predominant personality types of social members, social complexity, and technology. The smaller and more homogeneous the group, the less the need for temporal precision. Hopi-speaking Pueblo Indians have no tenses for past, present, or future events, and they think of time not as a series of unique distinct instants but rather as cumulative events. Where identities are collectivist and individuals focus on the welfare of their groups as opposed to themselves, often they think in terms of long-term goals. An Iroquois chief describes how his people’s decisionmaking “relates to the welfare and well-being of the seventh generation to come” (Rifkin 1987, p. 65). Such cultures feature people-oriented polychronic time, which stresses human engagements and the completion of transactions rather than rigid schedules. The activities of individualistic selves, such as those in the United States, tend to be governed by monochronic time, doing things one at a time in observance of task-oriented schedules and procedures. Oriented toward immediate rewards, these people are obsessed with punctuality and deadlines (Hall 1983)—and are demeaned when higher status others make them wait (Schwartz 1975).

As the primary form of work historically shifted from the land to the machine, the rhythms of social life were decreasingly dictated by natural times (e.g., cycles of day and night and the seasons) and increasingly by artificial times, such as the sixty-minute hour or the seven-day week, which have no bases in nature. With social differentiation and specialization evolved separate institutional realms, each with its own time schedules, rules, orientation toward the future and past, and patterns of change (e.g., cycles of growth and decay and oscillations between political liberalism and conservatism, bear and bull markets, and religious revivalism and secularism).

Given the growing importance of time, social institutions invariably sought its control through their creations of duration, succession, temporal location, and uniform rates of occurrence (Zerubavel 1981). Religions created prayer times and holy days (to distinguish themselves in time as well as space, Muslims claimed Fridays, Jews Saturdays, and Christians Sundays). One of the early acts of the First Republic of France was to alter time to create a more rational secular society. In 1793 the French Revolutionary calendar was adopted, with ten-day weeks, ten-hour days, and 100-minute hours. In Britain and the United States, national railroad schedules required uniform time because each town could no longer have its own noon when the sun was directly overhead. In 1883, Standard Railroad Time went into effect, creating five time zones to replace fifty regional times. A year later it was made the national legal time. Finally, with the increased rationalities of bureaucratic organizations, time became increasingly regularized and scheduled owing to greater needs for coordination and deadline-dictated precision.

Institutional differentiation was accompanied by the proliferation of social roles, which have become increas-
ingly age graded over the past six decades (Chudacoff 1989). Single-room schools, for instance, became age-segregated classrooms. Each of these roles, in turn, came with its own “social clock” and associated age norms. To be thirteen and still in the third grade is to be “behind schedule” and a source of shame; to be a thirteen-year-old college junior is to be “ahead of time” and a source of esteem. Sequences of these age-graded roles provide biographical pathways and timetables. In the case of the family, there exist normative “best times” for the length of courtships and when to first marry and begin parenting. In addition, there are normative patterns for how individuals’ various roles are to be synchronized, such as not getting married before completing junior high school.

Finally, substantial social science research has been devoted to individuals’ subjective experiences of time. Temporal orientations are, for instance, shaped by positions within the class structure, with the future-oriented middle-class being more likely than the present-oriented lower class to stress delayed gratification and thriftiness in their children’s socialization. The passage of time seems to accelerate with increasing age, density of experiences, and approaching conclusions. Multiple and conflicting role demands produce the stresses of temporal scarcity. Excessive rates of social change, according to Toffler (1970), can produce “future shock.” Not surprisingly, mystical significance is attributed to senses of timeless-ness, such as athletes being “in the zone” and in religious depictions of deathless eternities.

TIME ALLOCATION

The international comparative time-use surveys organized by Alexander Szalai (1966, 1972) are usually seen as the first modern time-use measurements. These surveys were followed by an increasing number of time-use surveys in many countries. Initially, these data were used descriptively for the valuation of household work and for information about leisure activities, commuting, and travel behavior.

Table 1 gives the average shares of a day allocated to various activities for both males and females aged twenty to seventy-four over two years for three European countries and the United States. Depending on the country and year, market work occupies on average about 15 percent of all available time, as does household work. Tertiary time, about 45 percent, is mostly sleep and personal activities, while the remaining 25 percent is devoted to leisure.

Economic analysis of the rationale for time allocation was inspired by the pathbreaking work of a group of economists at the University of Chicago. They were led by Gary Becker (1965), who saw the household as a unit that produced utility giving commodities from market goods and time input from household members. For surveys of the first decades of time-use analysis, see F. Thomas Juster and Frank Stafford (1991) and N. Anders Klevmarken (1999).

Becker’s revised theory of choice assumes that a household derives utility from commodities, say $Z_i$, $i = 1, \ldots, m$, such as meals, a clean house, sleep, and going to a movie, which are produced by the household according to the household production functions,

\[
\begin{align*}
T_j &= t_i Z_i, \\
x_i &= b_i Z_i. 
\end{align*}
\]

The functions specify how much input of market time, $T_j$, and goods, $x_i$, is needed to produce $Z_i$. (The proportionality factors $t_i$ and $b_i$ are not necessarily constant.) The household is assumed to maximize utility subject to its budget and time constraints. These two constraints are not independent because time for consumption can be converted into money income by allocating more time to market work. The two constraints can be combined into one,

\[
\sum_{j=1}^{m} p_j x_j + \omega \sum_{j=1}^{m} T_j = V + T_0. \tag{2}
\]

Total expenditures on market goods and household production time valued at the wage rate $\omega$ add up to the sum of nonlabor income $V$ and total time $T$ valued at the wage rate. The latter sum has been called full income. Substituting (1a,b) into the constraint (2), it becomes,

\[
\sum_{j=1}^{m} (p_j b_i + t_i \omega) Z_i = V + T_0. \tag{3}
\]
The expression in parenthesis is the full price of the \( i \)th commodity, and it is the sum of the prices of the goods and the time used per unit of the commodity \( t \). The price of time input is the earnings forgone by using time to produce a unit commodity rather than to work in the market. If all \( t_i \) are zero, the model reduces to a conventional model of consumer choice. Becker's model thus generalizes the conventional model by including the cost of time input to produce the utility-yielding commodities.

If the wage rate, the time cost, and the cost of market goods are fixed, it follows from the maximization of the utility function under the constraint (3) that marginal utility is proportional to the full price at maximum. We can now derive a number of predictions from this model: An increase in the wage rate will increase earnings forgone, and the full price of time-intensive commodities will increase more than that of good-intensive commodities. It follows from basic choice theory that the consumer will substitute away from time-intensive commodities and toward good-intensive commodities if the increase in the price of time is income compensated. At the same time, consumption time is freed for market work, which will increase. The effect of an uncompensated increase in the wage rate will depend on the relative size of the substitution and income effects.

If productivity of consumption time increases—that is, if \( t_i \) decreases—the relative price of time-intensive commodities will decrease, and consumers will substitute toward these commodities. For instance, when time-saving techniques are introduced into household work, we do more washing, cooking, and so on than we otherwise would have done. Whether or not we use less time in these activities will, as usual, depend on the relative size of the substitution and income effects, but if these commodities also become more good intensive, more market work is needed to generate the income required to buy the goods that go into these commodities.

Becker's model is a good conceptual model for theorizing about time allocation, but it has weaknesses as a model for empirical work: One and only one good contributes to each commodity; the wage rate and the time and good productivities are not necessarily fixed and independent of the consumer's choice; and the definition of a commodity is far from obvious. The model has been generalized to cope with these problems, but a more difficult problem is that the amount produced of each commodity is difficult if not impossible to observe. Without observations on the output from household production, it is in general not possible to identify preference parameters separately from the household production functions. All we can do is estimate mongrel time-use functions that depend both on preferences and household production technology.

In Becker's model, the household is treated as a single decision-making unit, and there is no place for the separate decisions of the household members. Although Becker obtains some results from his model concerning the division of labor within a household—for instance, those who are more efficient at market activities use relatively less time at consumption activities—this issue is better analyzed within a bargaining model (see, for instance, the survey by Behrman [1997]).

Time allocation is not only an issue of how many hours of the twenty-four-hour day or of the 8,760 hours of a year are spent on various activities; it is also an issue of when in a day or in a year various activities are done. One could also extend the domain of time allocation research by asking how much time is spent with whom? These issues have only recently attracted the interest of social scientists, but it is clear that when we do things and

**TIME AND MOTION STUDY**

Time and motion study, or motion and time study, is a basic set of tools used by industrial engineers to increase operational efficiency through work simplification and the setting of standards, usually in combination with a wage-incentive system designed to increase worker motivation. Originally developed to drive productivity improvement in manufacturing plants, motion and time study is also now used in service industries.

Motion and time study is associated with the so-called scientific management movement of the late nineteenth and early twentieth centuries in the United States, primarily with the work of industrial engineers Frederick Winslow Taylor (1856–1915), Frank B. Gilbreth (1868–1924), and Lillian Gilbreth (1878–1972). Some time studies had been conducted before Taylor, particularly by French engineer Jean Rodolphe Perronet (1708–1794) and English economist Charles Babbage (1791–1871), both analyzing pin manufacturing. However, modern motion and time study was developed as part of the scientific management movement championed by Taylor and eventually became known as *Taylorism*.

The foundation of Taylorism is a system of task management in which responsibilities are clearly divided between managers and workers. Managers and engineers engage in planning and task optimization, primarily through motion and time study, while workers are responsible for carrying out discrete tasks as directed. The Gilbreths sought to find the best method to perform an operation and reduce fatigue by studying body motions, attempting to eliminate unnecessary ones and simplify necessary ones to discover the optimal sequence of motions. The Gilbreths developed the technique of *micromotion study*, in which motions are filmed and then watched in slow motion. Taylor incorporated early research from the Gilbreths in his *The Principles of Scientific Management* (1911), and subsequent industrial engineers further developed the Taylorist system.

Taylorism played a key role in the continuous productivity improvement generated by the Fordist model of work organization. The Fordist model, which is based on the supply-driven, mass production of standardized goods using semiskilled workers, achieved efficiency improvements via scale economies and detailed division of labor, both accomplished through the Taylorist separation of conception from execution, in which managers plan tasks that workers execute.

Taylor argued that such a division of labor between management and workers was a form of “harmonious cooperation” that ultimately removed antagonisms from the workplace and benefited both managers and workers. However, this process of separating conception from execution is often understood as a form of de-skilling, and Taylorism has been rejected by unions, who have denounced it as a form of speedup that harms workers and hence quality and productivity.

Debates about the effect of motion and time study on workers continue today in discussions of post-Fordism, particularly *lean production*, which employs motion and time study to set standards and achieve continuous improvement in work processes, but in a context of demand-driven production without large buffers of in-
process inventory. Some workers and commentators argue that motion and time study under lean production is simply a form of work intensification that is detrimental to workers, while others argue that under lean production workers are able to contribute to problem solving and standard setting and thus prefer motion and time study under lean production to that under Fordism.

Underlying each system is a theory of worker motivation—that workers need to be coerced (in the Fordist model) or that workers want to do their best and are interested in more intellectual activity (in the post-Fordist model). In reality, there is more likely a distribution of different motivations across workers, and worker well-being is likely to depend more on the interaction between individual orientations toward work and how a given set of methods such as motion and time study are applied in a particular work context.

TIME ON THE CROSS

Robert William Fogel and Stanley L. Engerman’s two-volume revisionist study, Time on the Cross: The Economics of American Negro Slavery, is the most widely known and controversial work ever written on the subject of slavery. Indeed, it is arguably the most widely known and controversial work ever written in the entire field of economic history. The celebrity and controversy surrounding the publication of Time on the Cross in 1974 were related not only to its conclusions, but also to its methodology and rhetorical style, and the study has continued to spark debate since it was first published.

By the early twenty-first century, the field of economic history had lost much of the vitality it had in the 1970s. It may therefore be difficult for some to imagine a time when a technical work such as Time on the Cross could command space in mass-circulation newspapers and magazines such as the New York Times, the Wall Street Journal, Time, and Newsweek, and when economic historians made the rounds on the TV talk-show circuit. But Time on the Cross represented a kind of harmonic convergence of method, subject, authors, readers, and cultural milieu.

During the 1960s the venerable field of economic history was reinvented, mainly by small cadres of economists who explicitly and self-consciously brought economic theory, mathematics, and formal methods to a field that had previously been dominated by scholars trained in history departments and in traditional historical approaches. As a result, practitioners of the “new economic history,” such as Fogel and Engerman, spent much of the 1960s and 1970s revising and reinterpreting standard accounts of U.S. economic history. Although both Fogel and Engerman wrote on other topics, from the late 1960s on, they, along with many of their graduate students, worked assiduously on the economic history of the “peculiar institution” of slavery. In so doing, they turned the field of slavery studies upside down.

In 1974, the year Time on the Cross was published, the general consensus on slavery among historians of the American South was that slavery was a singularly exploitative, inefficient, and unprofitable system of labor organization. Slaves themselves were viewed as reluctant, recalcitrant, and inefficient workers, and the consensus was that their material lives were pinched, their emotional lives were stunted, and their family lives were disjointed and transient, if not incidental. For their part, slaveholders were viewed as “traditional,” or “paternalistic,” and nonentrepreneurial (or even anticapitalistic) in mindset and behavior. They were believed to be more concerned with aristocratic trappings and conspicuous consumption than with production, prices, and the bottom line. Moreover, despite scholarly outliers such as Frank and Harriet Owsley, who called attention to the importance of yeoman farmers and small slaveholders in the region, most students of slavery in the American South focused their attention on large planters, and this narrow focus served to render normative what was actually a very small and exceptional group. Furthermore, slavery and the slave system were said to have had deleterious long-run developmental consequences for the South as a region, rendering it poor and backward, particularly in comparison to the northern part of the United States.

Fogel and Engerman challenged all of these positions and more in Time on the Cross. Basing their “iconoclastic” findings on “the application of quantitative methods” (principally neoclassical economic theory, statistics, and applied mathematics) to historical materials, they concluded, among other things, that slavery was an efficient, profitable, and vibrant system of labor organization; that
African American slaves labored hard and purposively, sharing much the same work ethic that motivated free Americans; that Southern agriculture was highly productive—even more productive than agriculture in the North; that Southern slaveholders, including planters, were capitalistic, entrepreneurial, and bullish on the future; and that slaves, though exploited to a degree, enjoyed relatively good material living standards and, generally speaking, were able to sustain stable families and family ties. More broadly, they claimed that the slave economy of the South was not only healthy and growing rapidly in the antebellum period, but that it was also, in comparative terms, one of the most modern and advanced economies in the entire world at that time.

After a short honeymoon period of prizes, fawning reviews, and unstinting praise, *Time on the Cross* came under heavy critical fire from both traditional historians and some fellow “new economic historians.” Fogel and Engerman’s critics attacked from several different directions. Some criticized the authors’ approach and methods; others attacked both the assumptions and the evidentiary base upon which the authors’ findings were based; still others challenged the authors’ purportedly condescending and vainglorious rhetoric; and some questioned the implications of the authors’ findings, even if valid.

No wallflowers, Fogel and Engerman mounted a robust defense of their findings. In this effort, they were joined by their students and research associates, as well as by many other economic historians who found their approach, methods, and conclusions worth defending. The response to the publication of *Time on the Cross* was unprecedented in the normally quiet little field of economic history. Essays, both pro and con, proliferated in technical journals, and entire books were devoted to attacking Fogel and Engerman’s findings. Conferences and symposia on *Time on the Cross* were held throughout the decade of the 1970s, and for a time the study, or at least the nontechnical first volume of the two-volume work, became a staple on reading lists and course syllabi at American universities.

By the 1980s, *Time on the Cross* had taken many direct hits from critics and fallen out of favor among many students of American slavery. Although economic historians challenged parts of Fogel and Engerman’s argument on technical grounds—such as finding fault with some of their estimates, measurements, and assumptions—the most damaging blows were struck by traditional historians, who were particularly critical of Fogel and Engerman’s conclusions regarding the mindset and behavior of enslaved African Americans, and of what they viewed, rightfully or wrongfully, as the authors’ relatively benign depiction of the system of slavery itself.

Fogel issued an impressive rejoinder in 1989 with the publication of *Without Consent or Contract: The Rise and Fall of American Slavery*, which was followed in 1992 by two supplementary volumes of corroborative “technical papers” coedited by Fogel and Engerman. In the 1989 volume, Fogel, writing in a more subdued scholarly tone, defended much of the argument advanced in *Time on the Cross*, albeit with some qualifications, particularly in the section on the workings of the domestic slave trade.

Despite the study’s many strengths, *Without Consent or Contract* did not make nearly the splash made by *Time on the Cross* fifteen years earlier. By the 1990s, the “new economic history” was no longer new, and many of Fogel and Engerman’s “iconoclastic” 1974 findings on the economics of slavery seemed less jarring. Indeed, some had been more or less absorbed into the master narrative of American economic history.

If greater acceptance among the initiated helps to explain the rather subdued reception to *Without Consent or Contract*, the decline of economic history as a field of study was also a factor. By the early 1990s, few nonspecialists were paying attention to any work being done in this increasingly esoteric and marginalized area of study. Given this fact, it is not surprising that Fogel’s receipt (along with Douglass C. North) of the Nobel Prize in Economic Sciences in 1993 for “applying economic theory and quantitative methods to historical puzzles” did not rekindle the high-profile debate over *Time on the Cross*. Even so, outside of the spotlight, major figures in economic history, such as Gavin Wright, have continued to spar with Fogel and Engerman over issues raised in their combustible 1974 study.

TIME ORIENTATION

For centuries scientists and philosophers have been interested in the question of how the meaning of time is constructed and how people’s thoughts, feelings, and behaviors are shaped by time-related considerations. In the *Critique of Pure Reason*, for instance, Immanuel Kant (1781) provides an outline of the psychological significance of time. Thus time perception is an innate ability that shapes the way people perceive the world. The emphasis on innateness, however, does not imply lack of variability across individuals. Indeed most scientists and philosophers in the early twenty-first century concur that time is a social phenomenon that is likely to be perceived and experienced differently across individuals, situations, and cultures.

Another source of inspiration for contemporary theorizing on time is the work of Kurt Lewin (1951). According to Lewin, to understand the behavior of an individual at a given time, it is necessary to consider all the forces acting on the person at that time, including past experiences in similar situations as well as his or her expectations about the future. In line with this reasoning, most models of self-regulation maintain that influences on goal pursuit can be partitioned into three time frames, namely past experiences, present considerations, and expectations about the future. For instance, according to Albert Bandura’s (1997) self-efficacy theory, considerations about the past, present, and future are all consequential in determining people’s beliefs about whether or not they can perform a behavior. Thus when people engage in a goal-driven activity, relevant past experiences as well as expectations about the future can be brought to the current stream of consciousness and affect the way they pursue their goals.

Considerations about time come into picture when people make decisions as well. Many decisions in everyday life involve a trade-off between the immediate and the delayed consequences of actions. An employee receiving a bonus, for instance, may be torn between saving this bonus for retirement (delayed gratification) and spending it right away for vacation (immediate gratification). Confronting such a dilemma, some people focus on the immediate consequences of their actions (present-time orientation) and choose to spend the bonus for vacation; others are more concerned about the delayed outcomes of their actions (future-time orientation) and choose to add this bonus to the retirement fund. If people prefer one type of orientation over another repeatedly, these preferences may translate into habits or traitlike individual differences, which can in turn serve as cognitive biases toward being past, present, or future oriented.

Indeed various constructs have been proposed to address such differences in time orientations. For instance, the construct of consideration of future consequences (CFC) refers to “the extent to which people consider the potential distant outcomes of their current behaviors and the extent to which they are influenced by these potential outcomes” (Strathman et al. 1994, p. 743). Thus individuals low in CFC pay greater attention to the immediate consequences of their behaviors than to the delayed consequences of their behaviors. Individuals high in CFC, in contrast, pay greater attention to the delayed outcomes of their behaviors. The implications of CFC have been explored in a variety of contexts. For instance, future orientation has been consistently related to academic achievement, conscientiousness, less risk taking (e.g., safer sex), greater general concern with health and the environment (e.g., exercise frequently, consume less alcohol and tobacco, recycle), and more responsible consumption practices (e.g., less impulse buying). In line with this, present-time orientation has been shown to predict self-regulatory failures in a wide range of contexts. Presumably resisting temptations in a given context requires the ability to transcend that context, which is something future-oriented people seem more capable of doing than present-oriented people (for a review, see Strathman and Joireman 2005).

The fact that future orientation has been related to many positive consequences suggests that it may be the preferred time orientation. Indeed interventions have been designed to enhance future-time orientation and decrease present-time orientation. According to Philip G. Zimbardo and John N. Boyd (1999), however, encouraging people to focus on the future at the expense of the present time may not be a fruitful strategy because “life is lived in the present.” Focusing too much on the future may lead people to miss out on the meaning of life. Thus a balanced time orientation, where people flexibly switch temporal frames depending on self-regulatory resources, situational pressures, and personal appraisals, may prove to be more adaptive than a time orientation that is exclusively biased in one direction. The implication is that somebody can be high on both present-time and future-time orientations. Thus unidimensional scales may fall short of capturing the complexity of time orientation.
TIME PREFERENCE

A person with a time preference favors having a good sooner rather than later. As a result, the person also prefers having a good immediately to having a somewhat greater good later. Having a time preference amounts to discounting the value of future goods. It may be a source of improvident behavior later regretted: Because of a time preference, someone may spend next month’s rent money on a party and yet later, when the rent is due, would rather pay the rent than have had the party.

A leading member of the Austrian School of economics, Eugen von Böhm-Bawerk ([1884, 1889, 1921] 1959) appeals to time preference to justify payment of interest. Because people would rather have goods now than have identical goods later, he concludes that people who borrow capital should pay for its use. Refining this view, Irving Fisher (1930) attributes a community’s interest rate, an indication of the community’s preference for a good later to having a somewhat greater good sooner rather than later. As a result, the person also prefers having a good immediately to having the value of investment opportunity.

Böhm-Bawerk also uses time preference to explain profits from business ventures. An employer pays for labor and other factors of production. Payments occur before products are sold. The payments plus profits equal the products’ price. The profits are the employer’s compensation for postponing consumption of the amount of payments until the products are sold. The prevailing rate of profit depends on the prevailing degree of time preference and is equal to the prevailing rate of interest. Although short-term profits may not equal the rate of interest, long-term profits do. Economists elaborating this view argue that time preference is just a partial explanation of profits. Other relevant factors are the uncertainty of a product’s sale price and the influence of the supply of money on sale price.

Studies in psychology measure time preference. Harrell Chesson and W. Kip Viscusi (2000) infer the temporal discount rate of subjects from their choices. Subjects stated their choices between an amount of money in a fixed number of years and a gamble that pays either that amount of money in a smaller number of years or in a larger number of years. Chesson and Viscusi discovered that the subjects’ choices do not maximize time-discounted expected consumption. More surprisingly, they discovered that some groups have discount rates different from the rates commonly attributed to them. For example, smokers have a lower discount rate than nonsmokers do, and therefore they do not disregard future consequences more than others do. Chesson and Viscusi conjectured that smokers simply have tastes and perceptions of risk different from those of nonsmokers. Also, contrary to the common view that youth is impatient, Chesson and Viscusi found that older subjects have higher discount rates than younger subjects have. Shorter life expectancies may explain older subjects’ greater impatience to receive benefits.

Philip Trostel and Grant Taylor (2001) similarly argue that time preference increases as a person ages. Because of declining abilities, an aging person increasingly prefers consumption now to consumption later. Trostel and Taylor find that this effect is independent of a decline in the probability of survival.

Viscusi and Joel Huber (2006) examined revealed rates of time preference for public goods, such as water quality. They measured a person’s impatience to receive a public good and divided that impatience into a component due to time preference and a component due to the person’s perceived probability of not living long enough to benefit from the public good. According to their data, people display hyperbolic discounting rather than the exponential discounting most theorists assume. According to exponential discounting, if a good arrives in $T$ years and the interest rate is $r$, then the discount rate for the good is $\delta^T$ with $\delta = 1/(1 + r)$. According to quasi-hyperbolic discounting, the form of hyperbolic discounting that Viscusi and Huber investigated, the discount rate is $\lambda \delta^T$. 

Zeynep Cemalcilar
G. Tarcan Kumkale
with a parameter $\lambda$ such that $0 < \lambda < 1$. Their data show a high rate of time preference for immediate improvements and substantially lower rates of time preference for later improvements. This sharp decline in the rate of time preference is inconsistent with exponential discounting, but is consistent with hyperbolic discounting. The rate of time preference also varies among groups of subjects. Subjects who are old especially disliked delays in provision of public goods.

Economists characterize time preference as discounting future goods. Does time preference apply to goods that are dated, for example, dated commodity bundles? Because the value of a commodity bundle with a future date is already discounted for time, discounting the dated bundle for time results in an unwarranted double discount. For generality, philosophers characterize time preference as discounting future desires. A person with a time preference gives less weight now to satisfaction of a future desire than the person will give to satisfaction of the future desire when the desire occurs. The person’s discount applies to reasons for acts rather than to consequences of acts.

Philosophers and economists debate the rationality of time preference. Discounting future goods because of uncertainty is plainly reasonable, so the debate considers primarily the rationality of pure time preference, that is, discounting future goods just because they are future. Robert Strotz (1956) finds that clear-thinking people display pure time preference, and so concludes that pure time preference is rational.

Paul Weirich (1981) takes doing what one knows one will regret as a sign of time preference. Acting that way discounts future desires that generate regret. Foreknowledge of regret eliminates discounting because of uncertainty. Treating only future desires that are rational eliminates another reason for discounting. Suppose that in some cases it is rational to do what one knows one will rationally regret; then it is rational to have a pure time preference. One rationally prefers satisfaction of present desires to satisfaction of future desires just because the present desires are present. Basic goals change over time. Suppose that basic goals now and in the future are similarly rational although they differ. Then one may rationally not care now about satisfying a future rational desire. Suppose that one makes decisions using rational, all-things-considered desires that take account of all relevant reasons, including promotion of future desires’ satisfaction. A decision to perform an act is then rational, even if it leads to foreseen regret because of foreseen changes in basic goals. Doing what one knows one will regret, a manifestation of pure time preference, may be rational.

Derek Parfit reviews time preference’s treatment by Plato, Jeremy Bentham, and David Hume (1984, pp. 158–163). He characterizes time preference as caring less about the further future, and calls it a “bias toward the near.” If two future goods that are identical in features an agent cares about are separated by a period of time, a bias toward the near may lead an agent, relative to the first good, to discount the second good. Suppose that the discount increases as the first good comes nearer, and is highest when the first good arrives. Then the agent will have trouble keeping resolutions. The agent may for receipt of a sum of money agree to forego the first good and wait for the second good when both goods are far off. When the first good is imminent, the agent may pay a larger sum to have the first good rather than wait for the second. The agent’s temporal discounting causes a preference reversal.

Whether an agent is subject to such preference reversals depends on the agent’s type of discounting. If an agent has an exponential discount rate, and discounts the future at the same $n$ percent per unit of time, then relative to the first good, the second good always receives the same discount no matter how near the two goods are. Given an exponential discount rate, no preference reversals arise.

Many philosophers hold that a bias toward the near, which is independent of uncertainty concerning the future, arises from lack of imagination. Because of shortsightedness, an imminent pleasure is more vivid than a remote pleasure. The difference in vividness is a poor reason for a preference, however. A person with a bias for the near, for example, postpones pains at the cost of making them worse. It is irrational to care more about the nearer future just because it is nearer. Although Parfit acknowledges that because of a foreseen change in desires one may do what one knows one will regret (p. 189), he concludes that one should care about one’s self-interest in a temporally neutral way. This neutrality is incompatible with a pure time preference.

TIME SERIES REGRESSION

Consider two random variables, y and x. A regression of y on x is a model of the mean (or average) of y, conditional on values of x. It is thus a common statistical tool for analyzing how x might influence y. If a sample of values of y and x is observed in sequence over a period of time, this model is called a time series regression.

Time series regressions are distinct from cross-sectional regressions, in which observed values vary across similar units at a point in, or averaged across, time. For example, a researcher interested in the effect of income on consumer expenditures might rely on a cross-sectional regression model of expenditures of individual households during the year 2006 on household income during that same year. On the other hand, other researchers interested in overall consumer behavior might utilize a time series regression of aggregate consumer expenditures and income as they vary from year to year.

The distinguishing aspect of time series regression models is the common presence of serial dependence—a correspondence of values at different points in time—which does not typically arise in cross-sectional data. In time series regressions, there is a sense in which the order of the observations matters. Indeed, one of the important functions of time series regressions is to estimate and characterize this dependence on time and to determine how different variables fluctuate together over time. Serial dependence presents practical and conceptual problems that typically do not occur in cross-sectional applications.

Regression models of the mean of a random variable trace back to Francis Galton’s 1877 work on the hereditary effects of parent sweet pea seeds on their offspring. The first person to apply regression analysis to economic data is most likely Udny Yule (1895), who investigated the effect of types of government relief on pauperism in England in the late nineteenth century using cross-section data. Time series regressions and correlation analysis in economics begin to appear at about the same time in later work by Yule (1899) and in important studies by Reginald Hooker (1901) and John Norton (1902). This research grappled with many unique issues arising in time series regressions, such as trends and time lag effects (Klein 1997, chapter 9).

In a time series regression of y on x, the random variable y is called the dependent variable, because the model shows how its mean depends on the vector of k regressors, or independent or explanatory variables, x. Formally, we may write the regression model as

$$y_t = \beta'x_t + \varepsilon_t \quad t = 1 \ldots T,$$

(1)

where $\beta$ is a $k \times 1$ vector of constant parameters or coefficients (independent of time), $\varepsilon$ is a random error with mean zero and variance $\sigma^2$, and the sample period is assumed to run from period $t$ to period $T$. The subscript $t$ on the random variables denotes a particular point in time or period of time, so it is understood that these random variables vary over time. Since there are $k$ explanatory variables, the model is in general a multiple regression model. We interpret any particular $\beta$ coefficient as measuring the marginal effect of a change in the corresponding explanatory variable at time $t$ on the expected value of $y$ at time $t$, holding all other explanatory variables constant.

The model in effect decomposes the random variable $y_t$ into its mean conditional on $x_t$ and a random error. The conditional mean is given by $E(y|x) = \beta'x_t + E(\varepsilon|x) = \beta'x_t$ in light of the zero mean assumption of $\varepsilon$, and is assumed to be linear in the explanatory variables. If $y$ and $x$ are jointly normally distributed, this linearity assumption will hold exactly. Linearity implies that the marginal effects of the explanatory variables are independent of the values of these variables.

Given a sample of time series data on $y$ and $x$, the regression in (1) can be estimated. Estimation assigns specific values to the unknown parameters to identify the specific probability distribution that most likely generated this sample. Once the regression has been estimated, it can be used for making inference about theory, for forecasting, or for understanding the effects of policy actions.

The key assumption of the regression model is that the expected value of the error term is independent of the explanatory variables

$$E(\varepsilon_t | x_t, x_{t-1}, \ldots, x_1) = E(\varepsilon) = 0,$$

(2)

which is assumed to hold for all $t$ in the sample. This assumption is called the strict exogeneity of the vector $x$. It implies that the systematic relationship between $y$ and $x$ is fully captured by the model for conditional mean, so that deviations of $y$ from this mean are purely random. It follows that under strict exogeneity the error term is orthogonal to each of the regressors (the expected value of their product is zero) and that the covariances between the error and each of the regressors is zero. It also implies that least squares estimates of $\beta$ are unbiased in small samples—no
matters the size of the sample, the expected value of this estimator of \( \beta \) is equal to its true value.

A common case in which strict exogeneity does not hold is the autoregressive model, in which the conditional mean of \( y \) depends on its past values (for example, \( x_t = y_{t-1} \)). It should be clear that \( E(\varepsilon_{t-1} | x) = E(\varepsilon_{t-1} | y_{t-1}) \) does not equal zero in this case, as required by strict exogeneity. For such lagged dependent variable models, least squares estimators are biased in small samples. However, they will be unbiased in large samples, even when strict exogeneity does not hold if the regressors are predetermined: \( E(x_t \varepsilon_t) = 0 \) for all \( i = 1, \ldots, k \).

Both strict exogeneity and predeterminedness often break down in applications in the social sciences because of simultaneity bias. Such bias in estimating a time series regression occurs when the explanatory variable is influenced by the dependent variable or when common factors jointly affect both dependent and independent variables. Instrumental variables methods are a common approach to dealing with this problem; an instrument for \( x \) is a variable related to the dependent variable \( y \) only through its association with the explanatory variable \( x \). In general, the appropriate use of theory to guide the selection of instruments and other identifying restrictions is essential to solving the simultaneity problem.

Another important assumption of the basic time series regression model is that the error term is serially uncorrelated: \( E(\varepsilon_t | \varepsilon_s) = 0 \) for all \( t \neq s \). This condition means that past observations of the error term do not help forecast future values. If this condition holds (along with strict exogeneity), the least squares estimator of \( \beta \) is efficient in the sense that, of all the linear, unbiased estimators of \( \beta \), the least squares estimator has the lowest sampling variance. If the error term is serially correlated, least squares estimators of \( \beta \) will remain unbiased as long as \( x \) is strictly exogenous, but will be inefficient. Generalized least squares methods allow efficient estimation of \( \beta \) in the presence of serial correlation.

The autoregressive model with lagged dependent variables noted above is an example of a more general family of time series regression models that can capture the complex dynamic interactions that typically characterize time series data in the social sciences. A dynamic regression, sometimes called a distributed lag model, is given by

\[
y_t = a_0 + a_1 y_{t-1} + \ldots + a_p y_{t-p} + b_0 x_t + b_1 x_{t-1} + \ldots + b_q x_{t-q} + \varepsilon_t
\]

Note that this model specifically accounts for serial correlation in the dependent variable through the \( a \) coefficients, while allowing direct dynamic interactions with \( x \) through the \( b \) coefficients. For example, the coefficient \( b_3 \) measures the marginal effect (holding all other variables at all other times fixed) of a small change in the value of \( x \) three periods ago on the current value of the dependent variable.

Many time series variables wander over time without an apparent tendency to revert to mean. A dynamic process exhibiting this type of behavior is called a stochastic trend process, an example of which is the random walk. The best predictor of the current value of a random walk process is last period's value; the change in a random walk is unpredictable. Time series regressions that involve random walks, or more generally stochastic trends, may lead to invalid results and inappropriate inference.

Suppose that \( y \) and \( x \) each follow a random walk. As shown by Granger and Newbold (1974), a simple time series regression of \( y \) on \( x \) will reveal a strong correspondence between the two variables, even if they are, in fact, unrelated. That is, the estimated relationship between the two independent random walks will be spurious. The common solution to this spurious regression problem in the presence of stochastic trends is to either (1) estimate the time series regression after transforming the data into first-differences (i.e., instead of regressing \( y \) on \( x \), regress \( y_t - y_{t-1} \) on \( x_t - x_{t-1} \)); or (2) regress \( y \) on \( x \), but include lagged \( y \) and lagged \( x \) as explanatory variables.

372 INTERNATIONAL ENCYCLOPEDIA OF THE SOCIAL SCIENCES, 2ND EDITION
TIME TRENDS

A time trend, or time index, is the ordered set of natural numbers, for example, $t = (1,2,3,4 \ldots)$, that measures the time span between observations. The slope of a time-trend line represents the growth of a variable. For example, a time-trend line may be used to illustrate growth in production or industry earnings. To predict or explain economic variables, regression equations often use time trends. There are three main reasons for introducing time trends in regression equations that use time-series data. One reason is that a time trend captures the trajectory of the variable over time, providing forecasts of an economic variable. A second reason is that a time trend captures the effect of relevant variables in the regression equation that change over time and are not directly measurable. For example, in the estimation of production functions, Thomas Cooley and Edward Prescott (1973) use a trend variable as a proxy for technological change. A third advantage is that the time trend may capture specification error in regression equations that stem from functional form choice or variable aggregation.

Both linear and nonlinear time trends may be used in regression equations. The assumption in the linear-trend model is that changes will continue into the future at the same or similar rate. This assumption is particularly restrictive when only more recent observations contribute to explaining the future. A more flexible form is a linear trend under a spline-functional form (nonlinear time trend). The spline function jointly determines the trajectory and the memory of the series by allowing the slope of the time trend to vary across time. For example, the rate of change in the price of gasoline may vary across time. In this case, a time trend in a spline function allows the forecasting model to switch the slope parameters with the current economic regime. Both linear and nonlinear time-trend functions may be used in forecasting economic series such as prices, inventories, productivity, and consumption.

In addition to its uses in forecasting, a time trend serves as a proxy for nonmeasurable variables when explaining economic relationships, and it is commonly used in consumption models as well as in models that explain production, employment, and other factors of production. For example, food consumption is often specified as a function of personal disposable income, the price of food, the price of other goods, and a time trend. The time trend captures changes in consumer preferences.

A time trend also captures omitted information from specification error that stems from functional form choice or variable aggregation in the regression equation. The effectiveness of a time trend as a proxy for the omitted information from specification error depends on its correlation to included and excluded information in the regression equation, as well as the choice of functional form for the time trend in the equation. In a simulation study, Camilo Sarmiento and Richard Just (2005) provide evidence that a time trend is able to capture variation of the aggregation error (a special form of specification error) in aggregate consumption functions more effectively than methods based on conceptually accurate, time-specific approximations.

Clive Granger (2001) indicates the potential and unexplored uses of varying coefficients to approximate functional form in applications that use time series data. A time trend as an interaction variable in the model can be used to introduce time-varying coefficients and, thus, approximate unobserved functional structure in economic models, while reducing dimensionality issues in the specification of the functional form from the $m$-dimensional space (number of explanatory variables in the model) to the simpler one-dimensional space. The functional form for the time trend as an interactive variable in the regression equation could be linear or nonlinear. Significant empirical work and simulation analysis is needed in this area.

The popularity of a time trend in many economic models stems from its simplicity and intuitive interpretation. Statistical tests may be used to evaluate the effectiveness of time trends in forecasting and regression equations. Effectiveness depends largely on the application. The choice of time trend as a tool in model building involves not only whether to include a time trend and its functional form (spline function), but also whether to include it as an interactive variable.

TIME-AND-A-HALF

Since 1938 the U.S. Fair Labor Standards Act (FLSA) has required that most wage earners be paid one-and-a-half times their regular hourly pay rate for weekly hours
worked above forty. This rate is comparatively high. Whereas South Korea and most Canadian provinces also require a 50 percent overtime premium, France, Germany, and Italy require a smaller 25 percent, collective bargaining sets overtime premiums in the United Kingdom, and New Zealand has no overtime regulation. Countries' overtime regulations also differ in other aspects, such as the standard weekly hours beyond which the overtime premium applies, the types of jobs exempt from overtime regulations, and whether the regulation stipulates maximum weekly hours. An increasing number of countries allow employers to average work hours over the year rather than the week, greatly decreasing overtime payments.

The 1938 FLSA described its rationale as "the maintenance of the minimum standard of living necessary for health, efficiency and general well-being." It gained union support because it made union labor more competitive. However, an additional major motivation behind overtime regulations, both during the Great Depression of the 1930s and the high unemployment of Europe in the 1980s and 1990s, is to increase employment.

Whether overtime regulation indeed has a salutary impact on employment is ambiguous even in the short run. An overtime premium will immediately increase the marginal cost of additional hours per week, thus decreasing the weekly hours of those previously working more than forty hours, decreasing national work hours, and creating many jobs of exactly standard hours (e.g., forty). Whether this also increases employment depends on the substitutability between labor and capital and between different types of labor, scale effects, and on other labor regulations and institutions.

Once contracts can be renegotiated, however, economic theory suggests that an overtime premium can easily be undone by an implicit contract reducing the straight-time wage rate until workers get the same weekly pay and work the same hours as before the regulation. Consequently employment would not change. This does not apply to minimum or near-minimum wage jobs, because straight-time pay rates cannot fall sufficiently to offset the premium.

The best empirical work studies the impact of new or tightened overtime regulations. Average hours decline for those earning at or near the minimum wage or when straight-time wages are not allowed to fall for other regulatory or institutional reasons. Similarly the FLSA permanently decreased overtime hours (over forty) and increased the number of people working exactly forty hours, perhaps because of minimum wage jobs. Extensions of U.S. overtime regulations to new groups of more highly paid workers have not significantly affected weekly hours, corroborating theoretical predictions.

Studies of decreases in standard time in Europe generally find that standard time and average weekly hours move together. These studies, however, do not isolate exogenous changes and therefore should not be used to impute causality. The employment effects of lower standard hours or otherwise tighter overtime legislation in European, U.S., and Japanese labor markets have typically been found to be zero or negative, although these studies are subject to the same criticisms regarding causality.

**TINBERGEN, JAN**

**1903–1994**

When the Nobel Foundation initiated an award in economic sciences in memory of Alfred Nobel, it was no surprise that the first award in 1969 went jointly to Jan Tinbergen and Ragnar Frisch (1895–1937), two leading figures in the formation of the Econometric Society and the establishment of a new branch of economics early in the twentieth century.

Jan Tinbergen, like other economic scholars, began academic studies in science, but switched to economics and carried the mathematical background that became the hallmark of the new branch of economics. He made numerous original contributions to economic analysis, theory, and practice, but his greatest single contribution was in constructing the first working econometric models of a system as a whole, first for Holland, and later, for the United States. In the latter study, he was searching for a system that would enable economists to find the most satisfactory model of the business cycle. In that respect he tried to find a statistical representation of the ideas expressed by John Maynard Keynes (1883–1946) and his followers at Cambridge University during the years of the Great Depression in the 1930s. Although he did not uncover the secret of the cycle, he did succeed in laying the groundwork for empirical macroeconomic model building, in spite of Keynes’s dislike of Tinbergen’s approach, which Keynes did not fully understand. Tinbergen’s U.S. model prominently displayed the role of income distribution, the wealth effect, and some model specifications that would lead eventually to a well-estab-
lished relation between wages and unemployment. The wealth effect, which is now investigated on a broad scale, came about through Tinbergen's idea that price movements on the stock exchange played an important role in explaining the U.S. downturn after 1929.

It is important to note that Tinbergen made his pioneering contribution to macroeconomic model building in a dynamic framework at a time when usable national data were sparse and computational facilities were primitive. His work is being carried on and extended now with unusually better national accounts, frequency of data reporting, improved economic concepts, and enormous computer power with speed, all to make the tasks of econometric model building for the succeeding generation much easier for those who learned basics from Jan Tinbergen.

Tinbergen made early studies of income distribution and elasticity of substitution in international trade. He was dedicated to strong pacifist views. After World War II (1939–1945) he headed the Central Planning Bureau of the Netherlands and devoted his life to many worthy social causes; at the very end of his life he was soliciting help from colleagues and friends worldwide to support efforts against exploitation of children. He had a very systematic mind and conceived principles of economic planning, based on the clever separation, and distinctive properties of economic policy instruments and targets. Many politicians fail to make the appropriate distinction. In his exposition of policy formation in economics and in his work as director of the Central Planning Bureau, he made such distinctions clear.

Throughout his career, he trained many Dutch students in economics and also attracted many from abroad, especially after World War II. He is remembered as a person who led an exemplary life with simple tastes, great generosity, and a deep social conscience. In addition to his activities aimed at protecting children worldwide, Jan Tinbergen was a founding supporter of Economists Against the Arms Race (ECAAR) during the cold war. In line with his charitable instincts, during the immediate post–World War II period he generally carried cigarettes for a supplement to service fees such as taxi fares, even though he was a nonsmoker.

Tinto (Josip Broz) 1892–1980

Josip Broz “Tito” was born in Kumrovec, Croatia, on May 7, 1892. His first contact with political and social issues came in October of 1920 when he joined a union of metallurgy workers. In 1929, because of his active participation as political agitator, he was imprisoned for five years. After his release in 1934, he became a member of the Political Bureau of the Central Committee of the Communist Party, then located in Vienna, Austria, and in 1937 he became the Secretary General of the Central Committee of Yugoslavia.

After the German invasion of Yugoslavia in 1941, Tito became the national leader in the fight against the foreign occupation. It is during this period that his role as the leader of the Yugoslav people became clear, and he was soon able to attract a much wider base of support. His charismatic personality, his successful military guerrilla tactics, and his idea of a united Yugoslavia had a wide appeal. In addition to the Communists, he was joined by various resistance groups, such as the Chetniks of Draža Mihajlović, the Serbian resistance leader. After the liberation of the country in November 1943, Tito negotiated what would become the Socialist Federal Republic of Yugoslavia and became marshall of the new Yugoslav government.
TITO’S LEGACY
Tito ruled Yugoslavia as prime minister and chief of defense from 1945 until 1980. His ruling style appealed to both communists and noncommunists, and he unified Yugoslavia in a more liberal form of communism, commonly referred to as “Titoism.” However, this independence from mainstream communism created a schism between Tito and Joseph Stalin, the Soviet Communist Party leader, in 1948.

Although Tito succeeded in unifying the Yugoslav people, he faced many challenges in keeping this unification peaceful. Many viewed Yugoslavia as a single unified nation, but it was actually a federation of different republics and two autonomous regions. Tito was trying to hold this federation together by fighting nationalistic tendencies in both the Serbs and Croats. He also had to heal the wounds accumulated during the area’s war-torn past. One way Tito preserved the nation was through a more liberal economic policy that enabled the Yugoslavs to travel and often work in Western European countries. This policy contributed to the stability of the period. Tito’s open policy toward both the West and the East contributed to good relations with various nations that were otherwise politically opposed to each other. As a result, citizens of some communist European countries, such as Czechoslovakia or Hungary, could vacation in Yugoslavia, where they were joined by Western European tourists from Germany and Italy. Furthermore, in 1961 the first conference of the states of the Non-Aligned Movement was held in Belgrade. In 1971, Tito established a twenty-two member collective presidency, which was composed of the presidents of the six republics and the two autonomous provincial assemblies, in addition to fourteen members chosen from the republican and provincial assemblies for five-year terms. Tito was elected chairman of the new presidency.

While his policy of openness provided positive economic incentives to Yugoslavs, Croats and Slovenes benefited more than those in the other regions because of their proximity to Western Europe. Being the most economically advanced in Yugoslavia, the Croats and Slovenes resented having to transfer their profits to the poorer regions of Yugoslavia, which was a way for Tito to minimize discrepancies and redistribute wealth. This inequality between republics fueled increased nationalistic feelings from states such as Serbia and Macedonia, which did not benefit as much from the same trade. Croat and Serb nationalists who promoted independence were exiled, and many were assassinated in their new countries of exile, where they were planning insurrections to break up Yugoslavia. Many were also sent into forced labor camps in different parts of Yugoslavia.

Tito’s legacy came under threat in the 1970s. The economic downturn in the 1970s came as a consequence of rising foreign debt, inflation, and economic inefficiencies. Furthermore, Croatian nationalist secessionists were pressuring for independence, and Tito had to crack down on them by tightening the dictatorship. However, upon his death in 1980, the nationalist sentiments came to the surface and exploded in what became the Yugoslav civil war, which led to the breakup of the federation in the early 1990s.

YUGOSLAVIA AFTER COMMUNISM
As a consequence of ethnic tensions, the breakup of Yugoslavia in the 1990s was seen by some as inevitable after fifty years of Tito’s suppression of the Croat and Serb nationalist movements. First, Slovenia and Croatia, the two most economically advanced republics of the federation, were no longer willing to be tightly controlled by the central government and share their economic wealth through redistribution to poorer republics. The disappearance of Tito’s tight control also created an opportunity for Croats to declare independence, while the Serbian nationalists wanted to preserve a claim over Yugoslav territories, including Croatia. The war eventually spilled into the republic of Bosnia and Herzegovina, which to this day remains divided into cantons.

TOBACCO INDUSTRY
The tobacco industry’s main tobacco products are smoking tobacco (including cigarettes, cigars, and pipe tobacco), chewing tobacco, and snuff. The use of cigarettes as a means of consuming tobacco is relatively recent, beginning around the start of the twentieth century. Six states in the United States produce most of the U.S. tobacco: Georgia, Kentucky, North Carolina, South Carolina, Tennessee, and Virginia. Internationally, the United States is in somewhat of a unique position in that it is simultaneously a big tobacco-producing and a big tobacco-consuming country. On one hand, some countries, such as Malawi and Zimbabwe, produce tobacco at low costs but consume relatively little. On the other hand,
the European Union (EU) and Japan are heavy tobacco consumers but relatively little tobacco is grown there. About 100 countries produce tobacco, but Brazil, China, India, Malawi, Turkey, the United States, and Zimbabwe together produce over 80 percent of the world’s tobacco. China is the biggest producer of tobacco, while the United States is the biggest tobacco exporter in the world. In 2002, unfinished tobacco and tobacco product exports contributed $1.7 billion to the U.S. trade balance (Capehart 2001).

Tobacco use across the globe remains significant. According to the World Health Organization (WHO), globally, approximately half the men and about a tenth of women smoke. Smoking in developing nations has been increasing faster than that in the developed world. Since the 1960s, governments across the world have tried to control cigarette consumption (smoking) using various measures. Most governments now have some sort of anti-smoking policies in place. Initially these policies were driven by concerns regarding the health of smokers, while more recently the health of nonsmokers (dangers of second-hand smoke) has also become a concern.

SMOKING-CONTROL MEASURES
Generally policy makers have used both price and non-price measures to combat smoking. Whereas there is now a relatively good understanding of the effectiveness of tobacco control policies in developed nations, understanding of the effectiveness of such policies in developing nations is not so good. In addition, smoking behaviors of different population subgroups are slowly being understood. Price measures are primarily based on reducing smoking using higher cigarette prices driven by higher taxes. The responsiveness of cigarette demand to cigarette tax increases is at the heart of how effective tax-based smoking control policies can be. The effectiveness of price measures, however, may be limited by the habit-forming nature of cigarettes and their low price responsiveness of demand. Conversely, demand unresponsiveness provides greater opportunities for tax revenue generation by governments. Relatively speaking the few studies of developing countries have largely found a higher demand responsiveness implying that dollar-for-dollar, there may be greater smoking reduction opportunities in developing nations than in developed countries (Jha and Chaloupka 2000; U.S. Department of Health and Human Services 2000). Nonprice smoking control measures include numerous initiatives such as cigarette advertising bans (Saffer and Chaloupka 2000), health warnings on cigarette packages, and territorial restrictions (such as workplace and public-place smoking bans and restrictions on sales of tobacco products to minors).

In 1964 the U.S. Surgeon General issued a report warning about the negative health effects of smoking. While the United States was at the forefront of legislating smoking-related health warnings beginning in 1965, other countries have since enacted more restrictive requirements. There has been a ban on the broadcast advertising of cigarettes in the United States since 1971. In 1998, forty-six states in the United States and the key cigarette/smokeless tobacco products producers signed a master settlement agreement (MSA) to reimburse states for costs imposed due to negative health effects of smoking. The main provisions of the MSA include cash payments to the states, advertising restrictions, support for antismoking measures, and disbanding of tobacco-industry trade organizations. Payments were also to be made to tobacco growers to compensate them for the decrease in the tobacco demand (Capehart 2001; Viscusi 2002). In 2003 the WHO drafted a framework convention on tobacco control that included numerous restrictions on the sale and marketing of tobacco products.

EFFECTIVENESS OF SMOKING-CONTROL POLICIES
The extent of the effectiveness of these policy measures remains to be seen. Further, in spite of the stringent restrictions imposed by the various measures, technological advances, especially the spread of the Internet, make it virtually impossible to effectively regulate the marketing and sale of tobacco products. Effectiveness may be improved by comprehensive tobacco control policies in which lawmakers pay attention to consumption substitutability among tobacco products as more effective control policies are enacted on one product. At the macro level policy makers face the dilemma of replacing export revenues generated by tobacco products with other revenues. So how can curbs on domestic sales of tobacco be reconciled with encouragement of tobacco exports? The long-term future of the tobacco industry seems somewhat uncertain given all the attention and resources being devoted to smoking control. However, the habit-forming nature of their products, huge industry cash reserves, and the ability to launch newer tobacco products seem to promise a very long tobacco-control road.

Tobin, James

1918–2002

James Tobin, winner of the 1981 Nobel Memorial Prize in Economics, was among the leaders of postwar economics, with several significant contributions that now bear his name. Tobin was born in 1918 in Champaign, Illinois. Educated in economics at Harvard, he earned an AB in 1939, an AM in 1940, and, after a wartime role as a naval officer, a PhD in 1947. After three more years at Harvard, he departed for Yale’s economics department, where he spent the rest of his career save academic leaves and eighteen months in Washington as a member of Kennedy’s council of economic advisers. He remained an active member of the profession until his death in 2002.

Much of Tobin’s fame is due to his contributions to monetary economics and finance. As of the early 1950s, theorists had identified two main motivations for economic agents to hold cash: a transactions demand from consumers, and an investment demand based on portfolio considerations. While these two forces had been identified, there were no careful models to justify these demands by utility-maximizing agents. Thus, monetary theory lacked an answer to its most basic question: Why should anyone hold cash at all? In two pathbreaking papers, Tobin built models for each source of demand.

In a 1956 paper Tobin showed how to quantify the transactions demand. Starting with two simple forces—the transactions cost of making cash withdrawals and the opportunity cost of forgone interest—the model shows how the transactions demand is affected by interest rates. All other things being equal, an increase in interest rates induces consumers to make smaller, more frequent withdrawals, which lowers their average cash balances and the aggregate demand for cash. In combination with related work by William Baumol, this approach became known as the Baumol-Tobin model and still serves as a benchmark model of transactions demand.

Two years later, Tobin published another foundational paper on monetary theory, this time focusing on the investment demand for cash. In Keynes’s General Theory, the investment demand for cash was driven by investors’ subjective and nonrandom expectations of future interest rates, with investors holding cash rather than bonds if they expected interest rates to rise by some critical amount. This theory was criticized by several prominent economists for inconsistency with other parts of Keynes’s theory. Tobin (1958a) fixed this problem by introducing uncertainty into the portfolio problem, and then solving for the optimal portfolio of cash and bonds for an investor that cares only about the mean and variance of his portfolio returns. This “mean-variance” approach echoed the work of Harry Markowitz (1952) on portfolio optimization, with Tobin notably providing an important linkage between the financial decisions of individual investors and macroeconomic implications for money demand. Markowitz and Tobin shared their Nobel Prize in large part for this work, which provided the key building blocks for the foundational model of modern financial theory, the Capital-Asset-Pricing Model of William Sharpe (1964) and John Lintner (1965).

Tobin continued to build on the portfolio approach of the 1958 paper by adding more assets and increasingly complex economic environments for the portfolio-choice decision. This model-building continued for the remainder of his career. In two papers published in 1968 and 1969 (the first with William Brainard), investment in capital played a direct role in the portfolio decision. As a notational device, these papers used the letter \( q \) to represent the price of capital as normalized by its replacement cost. This appellation stuck, and Tobin’s \( q \) is now so ubiquitous that many economists cannot name the original papers from whence it came. In its simplest interpretation, a \( q \) greater than 1 indicates that the market price of capital is greater than its replacement cost, and thus rational investors would choose to build new capital rather than buy existing assets. When \( q \) is less than 1, investors would prefer the opposite. The large amount of information packed into this simple ratio has enabled an enormous and still-growing literature in macroeconomics and finance, all with Tobin’s \( q \) as the key valuation measure.

Early in his career, Tobin focused his research on the consumption component of macroeconomic demand. As in his work on monetary economics, Tobin attempted to build more rigorous microfoundations for Keynesian models, and in this attempt he ran into a stubborn econo-
metric problem: For large expenditures on consumer durables such as cars, most consumers have spending of zero in most years. In these cases, ordinary-least-squares (OLS) regression will give biased results. Tobin posited that such estimations require a combination of probit analysis with OLS, and in a paper for *Econometrica* (1958b) he derived an analytical solution for such a combination. Through wordplay based on various literary antecedents, this procedure, which remains a popular tool in econometric analysis, became known as the *Tobit* regression.

In addition to making numerous contributions to economics research, Tobin also maintained an active presence in policy debates. Following his service in Washington in the early 1960s, he generated a stream of policy proposals throughout the rest of his life. The most famous of these proposals, the so-called *Tobin tax*, achieved a life of its own in the twenty-first century over the objections of its originator. Tobin taxes—small taxes on financial transactions—were proposed by Tobin as a possible mechanism for reducing speculation and volatility in foreign-exchange markets. While this proposal never garnered much empirical support and was never an important plank in Tobin’s policy platform, his academic reputation made his name a valuable asset for antiglobalization activists, who saw Tobin taxes as a way to reduce international trade. In the last years of his life, Tobin actively distanced himself from this interpretation of his proposal and affirmed his lifelong support for free trade.

Tobin’s Q

Tobin’s Q is the ratio of the stock market valuation of firms to their “replacement” costs. Economists going at least as far back as Thorstein Veblen have noted the possibility of a discrepancy between the stock market value of firms and their replacement costs. Veblen conceived of a historiography of “capital,” whereby *capital* took on different meanings in accordance with various historical periods. In reference to the competitive phase of nineteenth-century capitalism, Veblen understood that crisis resulted from a “readjustment of [capital] values” ([1892] 1998, p. 112). New technologies made existing capital installations obsolete so that the “nominal accepted valuation of the capital, on which its returns are computed, exceeds its actual value as indicated by its present earning capacity” ([1892] 1998, p. 112). Here, Veblen compares a measure of capital based on “putative” earning capacity to actual expenditures on plant and equipment. That is, he formulates a measure of Q, without actually naming the ratio. According to Veblen, misalignments of valuations produce a psychological “malady of affections” in the investing class, a psychological fact that produces industrial depression ([1904] 1978, p. 237). In the transition to the great monopolies established during the Great Merger Wave of 1897 to 1903, Veblen contended that high stock valuations relative to replacement costs (i.e., high Qs) were reflective of monopoly power and a “sabotaging of production.”

In stark contrast to Veblen’s contention that high Qs reflect a monopolistic restriction on output and investment, modern Q theory, as elaborated by William C. Brainard and James Tobin (1977), holds that high Qs are primary forces driving new investment ahead. Tobin and Brainard’s modern version of Q theory derives from John Maynard Keynes’s remarks in his *General Theory of Employment, Interest, and Money* ([1936] 1953). In this famous work, Keynes noted that stock market booms would encourage investment because new plant and
equipment could be “floated off on the Stock exchange at an immediate profit” (p. 151). In the aggregate, a Q greater than one indicates that the stock value of firms exceeds their replacement costs and so there is an incentive for greater investment. Conversely, stock market slumps should drag Q below one, dampening the rate of building because entrepreneurs could buy similar enterprises on the stock market for less than it would cost to build them.

**IMPLICATIONS OF Q THEORY**

As an investment theory, Q theory has two clear, potentially testable implications. First, stock market booms should encourage investment. Second, mergers and acquisitions should rise when the stock market slumps and should fall off during stock booms. The first implication—that investment should go up during stock booms—is a virtual truism in that stock booms generally occur during booms in the general economy. It is generally difficult, however, to measure the separate effects of causative variables when many causative variables move together. For example, high profits generally expand both stock valuations and investment, so it is difficult to isolate any separate effect of high stock valuations on investment. In early tests, Tobin found “a good relationship” of investment and Qs (1978, p. 425). Yet in more recent studies, models that have used Q as a variable to explain investment have fared no better and have often done worse than pared down models using variables other than Q (Chirinko 1993; McCarthy 2001). So it is uncertain whether Q theory operates on new investment as predicted.

The other implication—that mergers and acquisitions should move countercyclically to stock booms and busts—is clearly refuted by the evidence. In the stock boom years of the 1920s, the 1960s, the 1980s, and the 1990s, mergers and acquisitions expanded rapidly. And during stock market slumps, mergers and acquisitions declined, often spectacularly as in the Great Depression of the 1930s. Various explanations have been offered to explain these results. Some theorists have postulated that stock booms allow firms additional financing through stock issues or debt collateralized by stock, which together with merger promoters have encouraged more acquisitions (Du Boff and Herman 1989). Other theorists suggest that stock booms encourage a wider divergence in stock valuations of companies (Gort 1969; Shleifer and Vishny 2003), although such an explanation seems at variance with the fact that stock valuations decline much more severely over shorter periods of time than they expand during booms.

**MARGINAL Q AND MONOPOLY POWER**

In order to fully comprehend how Q operates on investment and mergers, theorists still need to derive credible estimates of what is termed *marginal Q*—the additional stock valuation consequent on additional capital installations. In regard to the building of new firms, the logic of Q theory makes sense if there is “free entry” into industries—that is, new firms can be built and sold on the stock market. But when existing firms have monopoly power, the predictions of Q theory make sense only if marginal Q and Q move together. In contemplating new investment, existing firms would ask if additional capital spending would enhance the share price of the firm by more than the cost of the investment. Estimates of marginal Q have been made, but these estimates have either relied on assumptions of perfect competition in product markets (Hayashi 1982) or assumptions that conceive of capital as separate from technological change (Abel and Blanchard 1986). These assumptions are clearly unrealistic in an economy dominated by oligopolies, which install plant and equipment that often embody certain specific kinds of technology.

Monopoly power permits a divergence of marginal Q and Q. If marginal Q could be estimated accurately, then Q theory might well be able to better predict investment as well as mergers and acquisitions. If existing firms bumped up against new investment limits during stock booms (if marginal Q fell off), then this might explain why mergers and acquisitions expand during these same stock booms (Medlen 2003). Brainard and Tobin (1977) argued that marginal Q and Q moved together, but in the absence of any credible estimates of marginal Q, the question is still open.

Q theory has also been used to gauge monopoly power (Lindenberg and Ross 1981). Industries that have persistent monopoly power would presumably enjoy abnormally high profits over time. Given that industries with persistent monopoly power are protected against new entrants, such industries should exhibit high Qs. Conversely, in competitive markets, the Q ratio should approximate one; if “free entry” exists, then any abnormally high profitability would soon be eroded as new entrants came into the market.

In addition to theoretical problems, Q theory also contains unresolved measurement problems—particularly regarding the “replacement costs” of assets. With ongoing technological change, many assets would not be replaced at all. So the measurement of replacement costs might well be of questionable value. Some theorists also question whether the concept of replacement costs make sense in an information age in which capital often takes the form of knowledge, inclusive of the knowledge of in-house specialized workers (Bond and Cummins 2000). In addition, the very concept of marginal Q has been questioned on the basis that theorists have not yet fully understood the time path of new investment, a necessary precondition for
any possible measurement of marginal Q (Caballero and Leahy 1996).

TOBIT

Following James Tobin’s 1958 article “Estimation of Relationships for Limited Dependent Variables,” the tobit is a statistical model that is used to estimate the relationship between a limited dependent variable (y) and a vector of explanatory variables (x), usually by the method of maximum likelihood. The tobit model is warranted when the variable y is censored (i.e., when it is observed for some values above or below a certain threshold, but not in the remainder of the data). The term “tobit” was derived from Tobin’s name and by adding the suffix “it,” as for the 1964 probit model by Arthur Goldberger.

For example, a tobit model can be used to estimate the relationship between the number of hours worked (y) and education, age, gender, race, number of children, and so on (x). In this case, some individuals do not work at all (y = 0) while some work (y > 0), but education, age, gender, race, and the like are observed for all individuals, so that the data is censored. The advantage of using the tobit instead of the usual linear regression model is that it yields unbiased coefficient estimates for each of the variables in x. Note that the censoring need not occur at zero, nor does it need to occur below a specific value of y; the tobit also accommodates censoring above a specific value of y, and in a two-limit tobit, the dependent variable is censored both below and above a certain range of y.

CRITIQUES OF THE TOBIT MODEL

The most important critique of the tobit model is that it does not allow for the set of variables used in explaining whether y is positive or zero (say, x_j) to differ from the set of variables used in explaining the value of y conditional on y being strictly positive (say, x_i). James Heckman introduced a model in his 1979 article “Sample Selection Bias as a Specification Error,” which allows such a specification as well as control for selection bias in applications. Heckman’s model (or “heckit”), however, requires the use of an instrumental variable that can be excluded on theoretical grounds from the estimated equation for the values of y that are strictly positive in order to explain selection into the uncensored sample. Additionally, the tobit model is inconsistent when the error term is not normally distributed (this critique also applies to the heckit model), or when the variance of the error term is not constant, (i.e., it has unequal variances).
In a thorough survey of the literature on the tobit, Takeshi Amemiya (1984) discussed the properties of the model and provided many examples and applications of the tobit. He also outlined various estimation techniques as well as possible departures from the usual statistical assumptions and discussed generalizations of—and extensions to—the basic tobit model. G. S. Maddala suggested in his 2001 book *Introduction to Econometrics* exercising caution when considering the use of the tobit model (i.e., researchers who wish to use the tobit model should make sure that the dependent variable is, indeed, censored).

**TOCQUEVILLE, ALEXIS DE**

**1805–1859**

The French statesman and political philosopher Alexis de Tocqueville was born July 29, 1805, in Paris and died April 16, 1859, in Cannes. Much of his life was devoted to scholarship and public service. He is most famous for writing *Democracy in America* (1835–1840), a sweeping and perceptive study of American democratic life. His other important work is *The Old Regime and the French Revolution* (1856). As a young man, Tocqueville studied law and began his public service by working at the courts in Versailles. Later in his life, he became active in French politics, holding several elected offices.

Tocqueville’s family was part of the French petite noblese and had suffered greatly during the French Revolution (1789–1799). Consequently, it is not surprising that he held some aristocratic sympathies, along with concerns about the hazards of democratic excess. Still, Tocqueville was intrigued by democratic society and its potential for advancing personal liberty. He was also convinced that the spread of democracy was irresistible. For this reason, he wanted to better understand its benefits and dangers. This interest led him to visit the United States between May 1831 and February 1832. His cross-country tour took him to seventeen of the then existing twenty-four states. He spent a great deal of time in the metropolitan areas of the Northeast. He also traveled through such regions as the Great Lakes, the Ohio Valley, the Gulf Coast, and the South Atlantic. After returning to France, Tocqueville spent several years reflecting on his experiences and doing additional research. During this period, he wrote *Democracy in America*, which was published as two volumes in 1835 and 1840.

*Democracy in America* is considered a classic study because of its shrewd insights into the psychological, sociological, political, and institutional nature of American democracy. The book covers an exceptionally wide range of topics dealing with the democratic condition. Underlying this extensive analysis, however, is a desire to safeguard human freedom by better understanding democratic dispositions, passions, and tendencies.

According to Tocqueville, the most fundamental characteristic of the democratic age is equality. Its effect on democratic society is ubiquitous in both the public and private spheres. “The influence of [equality] extends far beyond political mores and laws … it creates opinions, gives birth to feelings, suggests customs, and modifies whatever it does not create” ([1835–1840] 2000, p. 9). Moreover, it inspires a strong and ardent attachment among democratic citizens. The benefit of equality is that it expands the reach of liberty and opportunity. Consequently, it gives all citizens a chance to take more control of their own lives.

Although equality had a fundamental influence on American society, inequalities did exist. Slavery, in particular, was a well-established practice in the southern states. Tocqueville, however, viewed slavery as a practice in “retreat” and destined to be abolished. He claimed, “Whatever efforts the Americans of the South make to maintain slavery, they will not forever succeed. … Slavery amid the democratic liberty and enlightenment of our age is not an institution that can last” ([1835–1840] 2000, p. 363). Still, Tocqueville was pessimistic about the future of race relations in the United States. Regardless of how slavery ended, he foresaw “great misfortunes.” He believed that conflict between the races could only be avoided by isolation or complete intermingling. Once slavery ended, isolation would be impossible, but white racism would prevent significant intermingling. As a result, the races would be left in a condition of precarious coexistence, producing a dangerous struggle for power.
Tocqueville also felt that equality could become dangerous if taken to an extreme. When people become too enamored with equality, they will do anything to maintain it, including sacrificing their liberty. The idea of equality can also be dangerous because it lends a daunting form of moral authority to the opinions of the majority. Because everyone is considered equal, the larger number of individuals in the majority is equated with superior judgment and greater utility. The opinions of the majority carry such great weight that they can lead to political tyranny, social conformity, and intellectual monotony.

Tocqueville argued that two other democratic dispositions, individualism and materialism, can also be threats to liberty. These inclinations are dangerous because they cause citizens to lose interest in public affairs. Individualism compels people to isolate themselves from the greater society and withdraw into small groups of family and friends. Materialism leads people to focus obsessively on their own private prosperity and to disregard public duties. The neglect of civic responsibilities can result in the development of a paternalistic despotism. Personal rights and freedoms are hindered and enervated as citizens become entangled in a network of “petty, complicated rules” ([1835–1840] 2000, p. 692).

Tocqueville claimed that it is possible to overcome these and other threats to liberty with the proper institutions, mores, and values. The presence of numerous and robust civil associations, for example, serves to protect individuals from an overbearing government. An independent press informs the public and facilitates associational activity. Religions that are able to inspire benevolence and instill a strong sense of spirituality can help counter the influences of individualism and materialism. The concept of self-interest properly understood links the performance of civic duties with private advantage. Prudent political leaders protect liberty through statecraft and soulcraft. Educated citizens are aware of the seductive dangers of extreme equality. Tocqueville concludes by noting that the future of democracy is not predestined; the people will determine if equality will lead to servitude or freedom.

The Old Regime and the French Revolution is Tocqueville’s attempt to understand the origins of the French Revolution. It examines the nature of French society prior to 1789. His primary claim is that the revolution was prompted by the political centralization of the state. Moreover, the revolution itself was a failure because it also centralized political power. Although The Old Regime has not attracted the attention of Democracy in America, it is still considered an important account of the social conditions that led to the French Revolution.

Tocqueville’s ideas about the democratic condition continue to exert a considerable influence on contemporary academic and political discourse. Of particular importance are his discussions of unchecked individualism and the importance of associational membership, which are frequently referenced in scholarly research on civil society and social capital. His pithy observations about democracy and democratic life are often quoted by politicians and popular commentators. The continuing relevance of Tocqueville’s work should not be surprising. He provides a seminal and perhaps the best account of the dangers of democracy and its threats to liberty.

**TOILETS**

This article is concerned with indoor conveniences: both domestic home toilets and those in the workplace and public buildings. Technological and cultural factors are discussed to understand why everyone, in the West at least, thinks it is quite normal to have a flushing toilet inside the house.

The Romans installed toilets inside their villas over 2000 years ago. But indoor plumbing was not a feature of European cities until the time of Queen Elizabeth I, for whom Sir John Harrington installed the first valve-flushing toilet in the 1590s. The majority of the population used chamber pots or relieved themselves outdoors. The wealthy had no need of domestic toilets; they had chambermaids. The few toilets that existed comprised a “privy” at the bottom of the garden, or on the outside of the castle wall hanging over the river. Privacy was not a major consideration, and men, especially, could relieve themselves anywhere inside or outside the house.

It was not until the Industrial Revolution that toilet provision became an issue. It was no longer acceptable to throw human waste on the midden outside the house. The ruling classes saw it in their own interests to enact public health reforms and to build sewers and drains because cholera is no respecter of class distinctions.

The introduction of water-based sewerage systems required the installation of flushing toilets. New para-
digms of hygiene and social morality arose. The toilet had to be “tamed” and “domesticated” and brought inside the house from the yard. Toilet entrepreneurs such as Thomas Crapper in Britain, and John Randall Mann in North America, capitalized upon this new toilet market, for “every home should have one.” Design was based upon the “sit” rather than “squat” style of toilet provision and exported globally. Most people in the world still squat and have no access to modern toilets or toilet paper. To have a flush-toilet in your house is a sign of great wealth, with the increasing scarcity and privatization of water supply in developing countries.

Social prudery made it taboo directly to talk about bodily functions in polite company. Americans say they are going to “the bathroom,” (in a bathtubeless room?), the British ask for “the little room.” In Far East countries bodily functions are not seen to be as culturally and religiously dirty as in the West: So euphemisms are less necessary. Nevertheless, Japanese high-tech toilets that play music to cover embarrassing noises are popular with women users.

In the nineteenth century it was considered so shocking for a woman to need the toilet when out that little “away from home” provision was made for women. Women still have approximately half the number of toilet facilities as men, a last vestige of sex discrimination. Standardized toilet manufacturers make little allowance for different user group needs, in terms of ergonomic design. Factory and office workers also suffer from lack of workplace provision, and there is no constitutional right for employees to urinate during company time.

While householders invest in high-quality designer bathrooms, in contrast the poor quality and lack of public toilets has been the cause of great concern to user groups such as the American Restroom Association (ARA). The ARA argues the business case that “bathrooms mean business” as better public restrooms will result in more tourists, shoppers, and visitors coming to town, staying longer, and spending more.

Public toilets, because they are public, are contested spaces, offering anonymity and seclusion to drug users and deviant groups. News reports of people being born, dying, being raped, trapped, attacked, or arrested in toilets are frequent. They are one of the few places where complete strangers mix and share intimate facilities. They repel those worried about picking up a sexually transmitted disease; women warn their daughters not to sit on the seat for hygienic purposes. They attract men who are “cruising” (cottaging, or looking for a date): the subject of many sociological and criminological studies. Toilet closure is often seen as the way to reduce crime. But closure greatly inconveniences bona fide users, as evidenced by a new generation of research on the practical needs of women and other social groups that are disenabled by the design of the built environment.

One can judge a nation by its toilets. When visiting a foreign country, the first necessity that people are likely to look for is the toilet, and the image and smell remain with them. The nature of toilet provision is an indicator of whose needs are valued in society and what a society thinks about women, babies, children, workers, and its elderly and disabled citizens.

TOLERANCE, DRUG

Tolerance is a decrease in the effects of a drug dose following repeated administrations. Tolerance is central to the definition of chemical dependence to some drugs (e.g., alcohol, heroin, painkillers), with theorists assigning to tolerance, or the mechanisms that produce tolerance, an important role in the genesis and maintenance of addictive drug use. Drug tolerance can be a symptom of physical dependence and a contributing factor to the severity of the physical and psychological dependence on a drug. For example, as drug users develop tolerance, they have to progressively increase their level of consumption to achieve the “high” they used to feel with lower doses during their initial stages of experimentation with the drug. Tolerance can be described as a homeostatic mechanism, or an organism’s adaptive response to foreign substances. Unfortunately, tolerance may decrease the effectiveness of medication regimes, as in the treatment of chronic pain, epilepsy, or depression.
Drug tolerance has been studied as either pharmacological (physiological) or learned (psychological) phenomena. Pharmacological tolerance models distinguish between dispositional (or pharmacokinetic) and functional (or pharmacodynamic) tolerance. Dispositional tolerance refers to an organism’s increased ability to metabolize and distribute the drug in the body. Thus, with increased dispositional tolerance, more of the drug must be taken to reach a specific concentration at the receptor sites. On the other hand, functional tolerance defines changes in neural functioning that result in dose-response decrements at the receptor site (i.e., the receptor responds less to a given concentration of a drug). Functional tolerance that develops to the effects of the first or second drug administration is called tachyphylaxis or acute tolerance. Functional tolerance that persists after prolonged exposure is called acquired or chronic tolerance.

Psychological or learning models distinguish between operant (or instrumental) and associative (or classically conditioned) drug tolerance. Operant tolerance defines the acquisition of specific skills or responses that compensate for the disruptive effects of a drug on task performance. For example, with other influencing variables being equal (e.g., genetic sensitivity to alcohol), operant tolerance theory predicts that a person who habitually drinks and drives should make fewer mistakes while driving under the influence of a relatively high dose of alcohol than a person with the same level of alcohol-use history who rarely drinks and drives.

Associative or classically conditioned models of drug tolerance posit that environmental stimuli reliably paired with drug delivery become conditioned stimuli that elicit conditioned responses that reduce drug effects. Perhaps the most influential of the associative tolerance models is Shepard Siegel’s compensatory response model. In the 1970s and 1980s, Siegel conducted a number of highly influential studies to test a theory that predicted that conditioned stimuli can produce conditioned responses that are opposite to, and thus cancel or compensate for, the effects of drugs. The compensatory response model of tolerance has been used to explain why some heroin addicts may die from a heroin overdose despite having developed very high tolerance to the effects of the drug. Although overdoses are often a result of mixing heroin with other drugs, many overdose deaths appear to result from a sudden loss of tolerance. Noting that many heroin overdose deaths occurred after the drug was consumed in a new setting or a new set of circumstances, Siegel reasoned that tolerance to heroin must be partially conditioned to the environment where, and manner in which, the drug is usually taken. Therefore, taking the drug in a new environment would eliminate the presence of conditioned tolerance and lead to overdosing.

An important characteristic or difference between pharmacological and learned drug tolerance is their differential resistance to extinction following detoxification or discontinuation of a given drug administration regime. Associative drug tolerance can be maintained or “remembered” for long periods of time, whereas nonassociative tolerance disappears rapidly in the absence of a drug administration regime. This characteristic of associative drug tolerance has been linked to the construct of drug craving. Like tolerance effects, cravings can be elicited by environmental stimuli (e.g., the sight of a lit cigarette for the smoker), a phenomenon that can occur even after years of abstinence (as often reported by smokers). That is, craving and tolerance can be conceptualized as memories associated with drug effects. Future research examining the physiological mechanisms underlying the development of learned tolerance will be invaluable for the development of drug addiction treatments, as well as the creation of medications partially resistant to pharmacological and learned tolerance effects.

TOLERANCE, POLITICAL

In the social sciences, scholars have devoted a significant amount of attention to the conceptualization, measurement, and analysis of one of the primary domains of tolerance, political tolerance. Although disagreements about
the nature of political tolerance remain, most political theorists contend that it is one of the central tenets of democratic theory because democracies are predicated on the assumption that people with widely differing viewpoints should be able to express their opinions and participate in political processes.

The first major empirical work on political tolerance was published in 1955 by sociologist Samuel Stouffer (1900–1960). In *Communism, Conformity, and Civil Liberties*, Stouffer reported the results of two national surveys in which he found that most U.S. adults were unwilling to extend civil liberties to unpopular left-wing groups; community leaders, however, demonstrated greater tolerance than the general public. This presented a conundrum to many political theorists who had thought that widespread tolerance was necessary for sustaining a democratic society. Later studies provided a partial explanation: U.S. adults were very supportive of civil liberties *in the abstract*, but they were much less likely to apply them to specific groups and situations.

In a groundbreaking study published in 1982, John Sullivan, James Piereson, and George Marcus offered a significant reconceptualization of political tolerance. Sullivan and colleagues defined political tolerance as “a willingness to permit the expression of ideas or interests one opposes” (Sullivan et al. 1982, p. 2). Thus, tolerance presupposes disagreement with a particular group’s views. Tolerance is demonstrated when one finds a group’s views objectionable, yet *still* supports the rights of the group. Sullivan and his colleagues developed the *least-liked group* approach to measuring political tolerance, in which they first asked respondents to identify their least-liked group, and then asked whether they would be willing to extend certain civil liberties to the group (recall that Stouffer had focused on unpopular left-wing groups). Their research found that while the objects of intolerance had changed since Stouffer’s original study, the majority of U.S. citizens were still intolerant.

Extensive studies of political tolerance both in the United States and in countries such as Australia, Germany, Israel, New Zealand, and South Africa indicate that although the target (least-liked) groups may differ, the variables that influence tolerance tend to be the same. Individuals who support the abstract norms of democracy (e.g., free speech, majority vote) are more likely to be tolerant. Those who perceive a high level of threat from the target group, however, are less likely to be tolerant.

Tolerant stances tend to be associated with education (high), social status (elite), age (younger), religiosity (more secular), and, to a lesser extent, gender (males). Individuals who demonstrate low levels of dogmatism and authoritarianism and high levels of interpersonal trust also tend to be more tolerant.

Scholars have also identified contextual factors that promote or inhibit tolerance. Stable, longer-enduring democracies tend to provide an environment that supports tolerance; however, conflict, and particularly conflict that threatens one’s group identity, tends to decrease individual levels of tolerance.

**TOLMAN, EDWARD**

**1886–1959**

The American psychologist Edward Chace Tolman was born in Newton, Massachusetts, on April 14, 1886 and died in Berkeley, California, on November 19, 1959. He received a BS in electrochemistry from the Massachusetts Institute of Technology in 1911, and a PhD in experimental psychology from Harvard in 1915. He spent the bulk of his academic career at the University of California, Berkeley, retiring in 1954. In 1937 he was elected to the National Academy of Sciences.

Tolman entered psychology in the first years of John B. Watson’s behaviorist revolution, and he even dedicated his best-known book, *purposive behavior in Animals and Men* (1932), to the white rat, but he was never a radical behaviorist. Whereas Watson (and, later, B. F. Skinner) rejected mental states as explanatory constructs, Tolman emphasized molar behavior over molecular “muscle-twitches,” as well as the importance of goals and expectations intervening between stimulus and response. (Another neobehaviorist, Clark Hull, similarly stressed the importance of internal drive states.) Heavily influenced by Gestalt theory, and especially by Kurt Lewin’s notion of...
the “life-space,” Tolman viewed the behaving organism as acquiring a “sign-gestalt-expectation” that a particular behavior will achieve a particular goal in a particular “behavior space,” and a general “means-end readiness,” represented by a “belief-value matrix” to engage in similar behavior in the future, under similar circumstances. He construed the rat facing a maze, even on the first learning trial, as entertaining and testing a sort of hypothesis as to what it should do; as engaged in “vicarious trial and error” behavior as it considered the choice of turning right or left; and as actively “searching for the stimulus” that would indicate one choice over another.

The flavor of Tolman’s experimental work, and its implications, are best illustrated by his most famous experiment, on “latent learning” (Tolman and Honzik 1930). Over twenty trials, rats who were rewarded with food took progressively less time to traverse a maze, compared to a control group that received no reward. A third group received no reward for the first ten trials, and behaved no differently than the controls. But when reward was introduced in trial eleven, they showed a precipitous drop in running time, behaving just like the rats who had been rewarded all along. Apparently, these rats had formed a “cognitive map” of the maze as a whole, but did not act on what they had learned until they had an incentive to do so. This experiment shattered the traditional view that reinforcement was crucial to learning: Reinforcement may control performance, but learning happens even in its absence. By redefining learning as the acquisition of knowledge, which organisms—rats as well as humans—could use for their own purposes, Tolman’s “purposive behaviorism” set the stage for the cognitive revolution in psychology that began in the 1950s.

Tolman was a civil libertarian as well as a psychologist, and served for a time on the national board of the American Civil Liberties Union. Perhaps reflecting his Quaker background, in 1918 he was dismissed from his first faculty post, at Northwestern University, for publishing an article in a pacifist student publication; and in 1942 he published Drives Towards War, proposing a set of social controls that could produce a warless society. Nevertheless, he volunteered for military service in World War I, and was offered a commission in the army; and he worked for the Office of Strategic Services, forerunner to the Central Intelligence Agency, during World War II. From 1949 to 1950 Tolman led faculty opposition to a loyalty oath required by the Regents of the University of California. He (among others) was briefly dismissed from his post, taking shelter at Harvard. In Tolman v. Underhill (1955) the California Supreme Court invalidated the oath, and Tolman and the others were reinstated. In 1963, in recognition of his contributions to both the discipline of psychology and the cause of academic freedom, the building housing Berkeley’s Department of Psychology and the School of Education—an award-winning example of mid-twentieth-century modernism designed by Gardner Dailey—was renamed in Tolman’s honor.

TOOLS
Stanley Kubrick’s science-fiction film 2001: A Space Odyssey (1968) opens with a scene of early hominids hammering with bones, depicting primitive tool use. While we
Tools

might consider human tool use as beginning with stones shaped by man for specific tasks, it is likely that found objects such as sticks, stones, and bones were used much earlier than this. With the advent of tools being intentionally formed for specific tasks, tools not only assisted, but also represented, particular ways of doing things. In other words, the design of a tool reflects an understanding of how to use that tool and what effect using it can make on the world.

Broadly speaking, a tool is some object that extends the abilities of its user. Thus, a tool might be an object held by an animal’s claws or mouth that extends the animal’s ability to reach, hit, and so on. This extension is also a change in the animal’s movement and activity. It is interesting to note that tool use occurs in so few species; that is, it is the exception rather than the norm in animal behavior. The problem with defining tool use is that often there is little need to assume that the animal has a purpose in mind—it is perfectly feasible to assume that the animal is exhibiting a stereotyped pattern of behavior that is common across the species, or in other words, the animal has little choice but to act in this manner. As Benjamin Beck points out in Animal Tool Use: The Use and Manufacture of Tools by Animals (1980), it can be difficult to separate tool use from the myriad other activities that animals perform.

An obvious route around this dilemma is to consider the manner in which objects might be used to solve problems. One cannot write about tool use without mentioning the work of Wolfgang Köhler and his studies of captive chimpanzees. His studies are interesting for introducing Einsicht (“insight”) into the psychological literature. In his work, the chimpanzees were confronted with problems, for example, a piece of fruit was placed just out of reach and the chimpanzee was given two sticks. Köhler’s thesis was that, after a period of confusion, the chimpanzee had a sudden realization (or “insight”) that joining the two sticks would allow him to reach the fruit. However, subsequent research suggested that a chimpanzee, given two sticks, will spontaneously attempt to join them, as part of exploring and playing with them. Thus, it is not clear whether the “insight” led the chimpanzee to decide to join the two sticks, or whether joining two sticks provided him with a longer stick that he recognized could reach the fruit. On the one hand, if “insight” was at work, then one could assume that the chimpanzee spent some time mulling over the problem until realizing a solution—that is, viewing the solution to the problem as requiring cognitive activity. On the other hand, the physical activity of joining two sticks (because it was possible) could lead to the creation of a new object, which could have new properties that the chimpanzee could recognize. This seems to raise questions of perceiving the affordance of objects (in the manner suggested by J. J. Gibson) rather than requiring representation of a model.

There has been growing evidence from the neuropsychological community that images of objects that support grasping evoke different neural responses from other images (in both humans and apes). This suggests that the brain responds to objects that afford particular responses, such as grasping. Research from patients with apraxia (disorders of movement) suggests that objects are coded in terms of their appearance and also in terms of the sequence of actions performed with an object—lesions in specific cortical regions can impair one or another of these codings. An implication of this is that an object can be recognized as supporting a particular activity (e.g., a shoe or a stone can serve as a hammer), and that practicing the use of the object can create coordinative structures for expert performance (e.g., comparing an experienced carpenter with a novice sawing a piece of wood). This suggests that the use of tools is a complex combination of psychomotor skill with cognitive abilities to recognize objects as potential tools and to determine sequences of use of these objects.

Research on the formation of stone tools by early hominids often divides between theorists who suggest that the tools were being made to a template or model and those (more recently) who suggest that the tools could be fashioned by reacting to the appearance of the object as it was being shaped. This would be an extreme version of stone-tool creation in which the process of hammering the stone to produce a “tool” was repeated until something approaching a useful tool was produced. However, many surviving stone tools not only exhibit similar shapes, but also tend to exploit the properties of the stones being worked. This suggests that even if the toolmaker did not have a “template” of the final product, the activity was responsive to the gradually changing nature of the stone being worked. This suggests that the toolmaker was sufficiently dextrous to work the stone, and capable of recognizing the affordance of the stone as it was being worked. Consequently, rather than setting out to make a specific tool, the toolmaker might have selected a stone that would potentially yield a tool (thus, needing to recognize in an object not only the potential to be used as a tool, but also the potential to be worked into a tool) before beginning the process of working the stone. As this process unfolded, imperfections in the stone might result in unanticipated fractures that would cause the toolmaker to either abandon the stone or to modify the shape being worked. What is clear from analysis of early stone tools is that different tools were used for different purposes (often, collections of several different tools have been found on a site, implying the existence of a “tool kit” to support different activities).
If we accept that a tool, in any form, represents an extension of the user’s abilities, cognitive tools can also be used to replace or at least redefine these abilities. What is interesting is that the substitution is not simply a matter of one set of activities replacing another, for example, a calculator replacing the ability to perform mental arithmetic by the ability to enter numbers on a keypad. Rather, the tool itself represents the problem that one is trying to solve, together with the manner in which to solve it. Thus, the calculator buttons invite entering numbers, even when the sum can be more quickly performed mentally. The conclusion is that a tool is not only a physical object but also the embodiment of the solution to a problem, and it also suggests the best way to approach activity.

TOPOGRAPHY

Translated literally from its Greek roots of topos (place) and graphein (to write), topography means “the writing of place.” In modern usage, however, the term has taken on more complex significance. As J. Hillis Miller notes (1995, p. 3), the term has come to refer to both the practice of accurate, scientific representation of particular places on the earth’s surface and the actual configuration of those places. In social science, topographies (both representational and actual) are of interest to researchers investigating relationships between societies and local environments. Such studies are common within the disciplines of geography, anthropology, archaeology, and sociology, and are sometimes found within economics and political science. As the diversity of disciplines with topographical interests reveals, the term topography addresses a foundational aspect of human experience (place) and thus serves as a foundational category around which social inquiry can be organized.

The dominant modern usage of the term has been in reference to the material configuration of places on the earth’s surface, typically with an emphasis on physical geography rather than the built environment. As Robert Christopherson makes clear (2002, p. 338), topographical studies based upon this emphasis are marked by the observation and recording of landscape features such as hill and mountain relief (dramatic or modest), slope angles (shallow or steep), drainage patterns (wetlands and rivers), and terrain characteristics (rugged or smooth, vegetated or barren) for specific locales. The goal of such studies is to define regional topographies (in the material sense) and provide the environmental knowledge (through representation) needed to facilitate land use decisions appropriate to specific social and economic goals. For instance, as Scott Kirsch (2002) outlines in an essay on John Wesley Powell’s (1834–1902) survey of the Colorado Plateau and surrounding area in the 1870s, in the late nineteenth century the U.S. government was keen to gain knowledge of the arid region of the American West so that land and resource use decisions could be made for an expanding nation. In particular, Powell was charged with ascertaining the irrigation potential of the region for agrarian settlement. Due to the undulating and arid topography, he argued, the grid system of land allotment typical of the Midwestern United States was not suited to the area. Instead, he recommended that all lots should abut water sources, even if that resulted in the alienation of land in irregular shapes. By observing and recording the characteristics of the physical geography of the region and combining the information for presentation in cartographic form, Powell’s work provided distant decision makers with knowledge of local environmental conditions, thereby enabling the setting of social policies regarding land allocation and resource rights. Of course, this relationship between topographical information and land and resource use marks a variety of enterprises and activities. From hikers’ use of maps to navigate mountain ranges to military officers’ use of electronic geographical information to locate specific place-based threats and targets, understanding the material arrangement of the physical environment of certain locales is central to decision making and interaction with places.

While modern topographical studies have tended to focus on the material configuration of places on the earth’s surface in order to facilitate land and resource use, this has not been an exclusive orientation. The term topography has been seized upon by a variety of researchers in the social sciences and humanities who are interested in place-based human experience. The humanistic geographer Yi-Fu Tuan (1974) has written about the centrality of place to human experience, the appreciation of which he terms...
**Topophilia.** Eugene V. Walter, in an attempt to formulate a more general understanding of humans’ physiological attachment to place, has proposed the study of topistitics as a “framework to grasp the whole experience of space and place” (1988, p. 18). Asserting that “topistic inquiry seeks theories that represent and explain forces that make or break the integrity of located experience” (p. 18), Walter seeks to emphasize that places are more than the sum of their material components and that people’s interactions with places form a central front in inquiries into both environments and the human mind. And, in his work on the relationship between literature, philosophy, and place, Miller (1995, p. 4) deploys the term topography to question how particular ways of knowing places have been inserted into modern Western epistemologies through language. Noting that in modern usage topography shifts between signifying representations of places and signifying actual characteristics of places, he highlights the connections between the production of knowledge about places and the experience of them. In different ways, then, these authors and others have moved understandings of topographies beyond concern for merely the material configuration of places and instead highlighted the multiplicity of ways in which humans become attached to and interact with places.

In an essay that brings together the human and physical aspects of place through a historical materialist approach, Cindi Katz argues for a conceptualization of topography as the sociomaterial terrain produced by an ever-globalizing capitalism. She insists that topographical studies “encompass the processes that produce landscapes as much as they do the landscapes themselves, making clear the social nature of nature and the material grounds of social life” (2001, p. 720). Further, Katz argues, the production of topographies “simultaneously turns on, reveals, and specifies the intricate relations among discrete places.” As such, topographical studies “can provide literal and figurative grounds for developing a critique of the social and political-economic relations sedimented into space and for examining the range of social practices through which place is produced” (pp. 720–721).

Ultimately, Katz points out that this framework enables the development of a series of countertopographies. She envisions these as “linking different places analytically in order to both develop the contours of common struggles and imagine a different kind of practical response to problems confronting them” (p. 722). In combination, Katz’s conceptualization of topographies and countertopographies provides a resource for critical analyses of place that takes seriously the impacts of political and economic history in shaping local terrain.

As is evident from this survey, topography is a malleable and widely used term. With its focus on place and human understanding of it, the term and the studies organized around it are central to a comprehensive pursuit of social science. Whether material, social, or both, topographies (both representation and actual) mediate the lives people lead and help to define the places in which they are lived.

**TOPOLOGY**

In the social sciences, it is important to know if close-by models of human behavior and interaction entail close-by predictions. More precisely, the question is whether a sequence of models, which mirror reality in an increasingly accurate manner, yield predictions that converge to those that can be observed in the real world. Topology is a mathematical structure designed to express robustness, approximation, convergence, and continuity, and is thus useful in determining the relevance of a given social-science model.

For example, economies differ according to the endowments of individuals, the available production technologies, and the preferences of individuals over bundles of commodities. General Equilibrium Theory predicts the market prices that can emerge as a result of various combinations of these factors. The robustness of these predictions can then be tested through a consideration of a topological space of economies in which one can examine whether market prices change continuously with changes in the economies’ characteristics.
Similarly, in Game Theory, Nash equilibrium is a prediction of the strategies that players will choose noncooperatively as a function of their preferences over the outcomes entailed by strategy profiles. When considering a topological space of games, one can check how Nash equilibria vary with the game specification. Alternatively, Social Choice Theory, based on normative considerations, prescribes a strategy profile that the players should choose collectively (rather than noncooperatively) in the social situation at hand. In a topological space of such social choice problems, one can check if close-by behavior is prescribed in close-by situations.

Formally, given a space $X$ of model characteristics (or some other objects of interest), a topology is a system $T$ of open sets, which are subsets of $X$ with the following properties: (1) The union of any collection of open sets is open; (2) the intersection of a finite number of open sets is open; and (3) both the entire space and the empty set are open. The complement of an open set is called close. A space $X$ equipped with a topology of open subsets $T$ is called a topological space.

A pertinent example is the case in which the space is metric, i.e., when there exists a metric that defines the distance between any two objects in the space (such that the distance of an object to itself is zero; the distance from $x$ to $y$ is the same as the distance from $y$ to $x$; and the distance from $x$ to $z$ is no larger than the distance from $x$ to $y$ plus the distance from $y$ to $z$). In such a case, the unions of “open balls” constitute a topology (an open ball of radius $r$ around a point $x$ in the space is the set of points in the space whose distance to $x$ is smaller than $r$).

Moreover, a set $V$ is open if and only if every point $x \in V$ has an open ball around it contained in $V$.

Hence, if for some property $P$ of the model, the set $V$ of characteristics at which $P$ obtains is open, then the property $P$ is robust: When a characteristic $x \in V$ is measured with a small enough error, the measurement will still have the property $P$.

The idea of robustness, as captured by open sets, carries over also to families of economic models whose topological structure is so rich it cannot always be compatible with a metric. Financial models of dynamic investment in continuous time, and stochastic uncertainty—over objective circumstances, as well as over others’ uncertainties—are two important examples.

A sequence $x_n$ of points in the space converges to the point $x$ if for every open set $V$ containing $x$ there exists a stage $N$ beyond which all points $x_n, n \geq N$ in the sequence belong to $V$.

This definition of convergence applies not only to sequences, but also to nets. In a net $x_n$, the indices $n$ are not necessarily the natural numbers. Rather, they may form a directed system—a set where not every pair of distinct indices $n, n'$ is characterized by one of the indices being larger than the other, but where there always exists another index $n''$ that is larger than them both.

Convergence of sequences and nets depends on the richness of the topology. In the trivial topology, containing only the empty set and the entire space $X$, every net converges to every point. At the other extreme, with the discrete topology, in which every subset is open (and, in particular, every subset containing a single point is open), a net $x_n$ converges to $x$ only if for some index $N$ and onward $x_n = x$ for all $n \geq N$. Hence, the choice of topology expresses the extent to which the modeler views different points (or objects or model characteristics) in the space as distinct or similar. The more fine-detailed the distinctions are, the richer will be the topology, and fewer nets will be converging to any given point $x$.

When $X$ and $Y$ are topological spaces, we say that the function $f: X \rightarrow Y$ is continuous at the point $x \in X$ if for every net $x_n$ converging to $x$, the net $f(x_n)$ converges to the point $f(x) \in Y$. We say that $f$ is continuous if it is continuous at every point $x \in X$.

If $X$ is a space of model characteristics and $Y$ is a space of potential predictions, one would like the prediction function $f: X \rightarrow Y$ of the model to be continuous—otherwise a slight misspecification of the characteristics might yield wildly distinct predictions.

One can show that $f$ is continuous if and only if for every open set $W \subseteq Y$, the set $f^{-1}(W) = \{x \in X: f(x) \in W\}$ is open in $X$. Thus, the richer is the topology of $X$ and the poorer is the topology of $Y$, the more functions $f$ from $X$ to $Y$ are continuous.

**TORTURE**

As media accounts and images of torture, trauma, disaster, and rape permeate our daily lives, it is difficult to ignore the impact such destruction wields on the social fabric in which we live. Individuals directly affected by this devastation, such as refugees, asylum seekers, IDPs (internally displaced people), and illegal immigrants, struggle to piece their lives back together after enduring unimagin-
able cruelty and violence. The cruel and violent acts witnessed and experienced by these individuals come in many forms, one of the most common being torture. Though the word torture is commonly used without restraint in everyday language, its use should be clearly differentiated from words for inhumane and degrading actions that may fail to match the true definition of “torture.”

DEFINITIONS OF TORTURE

The two most frequently cited definitions of torture are the World Medical Association’s (WMA) 1975 Declaration of Tokyo and the definition given by the 1984 United Nations Convention Against Torture.

The 1975 WMA Declaration defines torture as: “The deliberate, systematic, or wanton infliction of physical or mental suffering by one or more persons acting alone or on the orders of any authority, to force another person to yield information, to make a confession, or for any other reason.” The 1984 United Nations Convention Against Torture expands upon this definition, distinguishing the legal and political components typically associated with torture:

Any act by which severe pain or suffering, whether physical or mental, is intentionally inflicted on a person for such purposes as obtaining from him or a third person information or a confession, punishing him for an act he or a third person has committed or is suspected of having committed, or intimidating or coercing him or a third person, or for any reason based on discrimination of any kind, when such pain or suffering is inflicted by or at the instigation of or with the consent or acquiescence of a public official or other person acting in an official capacity.

Currently accepted definitions of torture have two essential elements: (1) Individuals are placed in captivity and subjected to extreme mental and physical suffering; and (2) the captors have a political goal or agenda. In this way, torture as a legal definition can be distinguished from criminal acts of violence.

TYPES AND PURPOSE OF TORTURE

The most common types of torture are summarized in Table 1. Torturers use these techniques to achieve several main goals. The most obvious intention of torture is breaking down an individual both physically and mentally (frequently for military or political purposes). Secondly, torturers seek to spread collective fear throughout a particular community or culture in which the victim lives. Finally, the torturer seeks to deeply humiliate the victim’s society and community. The goal of torture is essentially to render the victim nonhuman.

Table 1. Most Common Forms of Torture.

| Beating, kicking, striking with objects |
| Beating to the head |
| Threats, humiliation |
| Being chained or tied to others |
| Exposure to heat, sun, strong light |
| Exposure to rain, body immersion, cold |
| Being placed in a sack, box, or very small space |
| Drowning, submersion of head in water |
| Suffocation |
| Overexertion, hard labor |
| Exposure to unhygienic conditions conducive to infections and other diseases |
| Blindfolding |
| Isolation, solitary confinement |
| Mock execution |
| Being made to witness others being tortured |
| Starvation |
| Sleep deprivation |
| Suspension from a rod by hands and/or feet |
| Rape, mutilation of genitalia |
| Sexual humiliation |
| Burning |
| Being made to write confessions numerous times |
| Being shocked repeatedly by electrical instrument |

Table 1. Most Common Forms of Torture.

One important act of torture, for example, that has only recently been recognized as such is rape, a frequently used torture practice during periods of conflict and genocide. A group with a particular agenda often executes systematic or wanton rape and sexual violence knowing that the long-term effects of this experience will be devastating to both the individual and his or her community. However, rape was only recognized globally as an act of torture after the international appraisal of violence that occurred in Bosnia-Herzegovina and Rwanda.

PSYCHOLOGICAL AND PHYSICAL EFFECTS OF TORTURE

Knowledge of the types of torture described in Table 1 enables medical doctors, mental health professionals, and other health-care workers to assess the medical and psychological impact of torture and determine appropriate treatment. Until very recently, the psychological effects of
torture have remained largely invisible. This is because of the combined effects of the difficulty of assessing mental symptoms in culturally diverse populations, the unsuccessful search by human-rights organizations for a unique “torture syndrome,” and the popular belief in some medical circles that extreme violence leads to the psychiatric diagnosis of post-traumatic stress disorder (PTSD). PTSD may be an appropriate diagnosis. However, this emphasis on PTSD has obscured the reality that the most common mental illness diagnosed in torture survivors is depression—often a serious and socially debilitating condition associated with serious medical consequences. While physical complaints in torture survivors are very common, usually these bodily complaints are the way people from various cultures express their pain and suffering.

Head injuries caused by beatings to the head with fists, clubs, or gun butts represent one of the most common physical effects of torture, leading to neuropsychological deficits that are rarely identified. Studies have shown that victims of all types of torture often experience persistent and pervasive sensory and memory deficits, cognitive impairment, chronic pain, and certain forms of motor impairment (as serious as paraplegia) as a result of their torture experience. Other more specific physical symptoms commonly reported include headaches, impaired hearing, gastrointestinal distress, and joint pain. Scars on the skin and bone dislocations and fractures are also typically observed.

Since sexual violence is a common form of torture, its effects, including increased risk for cervical cancer, human immunodeficiency virus (HIV) infection and AIDS, and a range of sexual dysfunction including impotence, must be identified and treated by medical professionals.

TREATMENT FOR VICTIMS OF TORTURE

Physicians and health-care providers throughout the world are frequently confronted with the need to identify and treat the physical and psychological impact of extreme violence and torture. It is estimated, for example, that 60 percent of individuals who seek asylum in the United States have been tortured, as have many refugees and migrant workers. A history of torture is common in various groups that have resettled in the United States and other countries during recent decades—Cambodians, Vietnamese “boat people,” and former Vietnamese prisoners of war (POW) who arrived in the 1980s; Central Americans who immigrated in the 1980s and 1990s; and recent arrivals from sub-Saharan Africa, the Middle East, and eastern Europe. Many newcomers enter the United States not only to find economic opportunities but also to escape violence and political instability at home.

Despite routine exposure to the suffering of victims of human brutality, many health-care professionals tend to be apprehensive about confronting this reality in their clinical work. Globally, clinicians often avoid addressing torture-related symptoms of illness, believing they will not have the tools or the time to help torture survivors once they have elicited their history. As a result of this resistance, survivors and clinicians may conspire to create a relationship founded on the avoidance of all discussion of trauma.

The most effective care for torture survivors must begin with awareness. Persons who have been tortured generally do not want to be treated simply as torture survivors. Rather, they prefer a holistic approach that addresses their current reality in a culturally sensitive way. Many characteristics of the patient’s background provide clues that torture may have occurred. As health-care practitioners become more empowered to ask questions such as, “Have you experienced extreme violence or torture?,” it becomes easier to identify and treat the pathological symptoms of such trauma.

Torture survivors often do not recognize any relationship between the torture and current medical problems they may be experiencing. When asked about specific events, patients are usually grateful that the clinician is aware of what they have suffered, is interested in their history, and is encouraging them to talk about their story. Though clinicians often fear a patient’s reaction to questions about torture, patients rarely become emotionally overwhelmed or lose control when such questions are asked. Some torture survivors, especially victims of sexual violence, may have been hiding their history out of feelings of shame or fear of stigmatization, and thus be grateful to talk to someone who cares. Others may come from cultures in which physicians are not expected to be interested in patient’s personal history.

RECOVERY FOR SURVIVORS OF TORTURE

Many torture survivors recover from torture with the help of spiritual and religious practices, work, and altruistic activities that benefit themselves, their families, and their communities. These self-healing efforts need to be strongly supported by society and its health-care and mental health-care institutions. Human beings are incredibly resistant to even the most horrifying acts of human cruelty. While the majority of torture survivors recover without professional help, some do not. It has been shown that these individuals can greatly profit from proper medical and mental health care that will facilitate their return to a normal life.

A broad range of individual treatments exist that include primary health care, physical rehabilitation of tor-
ture-related disabilities, and psychological interventions aimed at eliminating traumatic memories, nightmares and chronic depression. Healing of torture survivors is also maximized when governments and the international community acknowledge the injustice they have suffered (e.g., the Truth and Reconciliation Commission in South Africa).

TOTALITARIANISM

*Totalitarian* is a term employed by social scientists to describe a type of political regime that arose in the twentieth century. What is said to distinguish this type of regime from traditional forms of nondemocratic authority such as tyranny or dictatorship is the ability of the totalitarian state to establish and maintain a highly integrated social system that controls nearly every aspect of public and private life.

Social scientists have developed a theoretical model to delimit five essential features underlying this unique political system. First, the totalitarian state is organized around an all-encompassing ideology that subordinates all aspects of society to the logic of a teleological process that promises to culminate in the attainment of a perfect and final stage of humanity. In order to achieve the revolutionary goal, the totalitarian project systematically eliminates constraints on state power. In this manner, a totalitarian state aims to establish a permanent state of emergency (wherein the rule of law is suspended) as a legal norm, thus, in effect, codifying arbitrary power.

Second, totalitarianism destroys all social, legal, and political traditions that precede it. It transforms a pluralistic party system into the rule of a single mass party headed usually by a single dictator. The party aims to transform the ensemble of social relations into an integrated social totality by a process of perpetual revolution.

Third, if this “perpetual revolution” is to be carried out successfully, it must institutionalize a highly coordinated use of terror that shifts the epicenter of power from the army to the police. Totalitarian use of terror suppresses not only political opposition and all groups and ideas not subordinate to the substantive goals of the state, but also all social space traditionally beyond state control that exists among citizens. Such use of terror produces an environment within which individuals live with an extremely high level of uncertainty and unpredictability.

Fourth, such a regime monopolizes not only the armed forces, but all forms of mass communication as well. Seizing control over the means of communication allows the state to socialize and mobilize different segments of the population through the dissemination of mass propaganda. This mobilization entails the participation of individuals in state-sponsored social and political organizations that stage events and campaigns that often target an “enemy of the state,” usually entire categories of citizens that must be eliminated. Finally, the totalitarian state seeks central control and direction of the economy.

The two outstanding historical examples of totalitarian states are Nazi Germany, particularly during the years of World War II (1939–1945), and Stalinist Russia (1927–1953). Although most commentators agree on the totalitarian nature of these two states, there is no general consensus on what other states can be declared totalitarian, but such a list could arguably include fascist Italy under Benito Mussolini (1922–1943); Communist China, particularly during the Cultural Revolution.
(1966–1976); Khmer Rouge Cambodia (1975–1979); Augusto Pinochet’s Chile (1973–1989); the Argentine military regime of the 1970s; and North Korea since 1953.

CAUSES OF TOTALITARIANISM

There are a number of possible causes of the rise of totalitarian states. An historically specific explanation has it that the political and economic chaos in Europe that followed World War I (1914–1918) created a climate of fear and resentment that some popular governments and movements exploited in order to seize or consolidate state power. Fascist totalitarian regimes (Mussolini’s Italy and Nazi Germany) aimed at diverting attention from class conflict by ruthlessly repressing political strife and labor unrest and promoting a form of nationalism in the name of interclass solidarity. Communist systems, on the other hand, sought to end class struggle and inaugurate a classless utopia by repressing those opinions and actions deemed antithetical to a workers’ state.

Another argument holds that industrialization eroded traditional social values and familial, social, and professional bonds, thereby creating a gap that was then filled by the development of a modern mass society; the latter came to be distinguished by a uniform style of life reinforced by propaganda, advertising, and mass entertainment. In such a society, individuals severed from tradition become alienated and highly susceptible to totalitarian manipulation.

An explanation popular with libertarian theorists argues that the roots of totalitarianism can be found in the gradual growth of socialism in all industrial societies. Such theorists argue that because socialism requires states to direct and control the economy, it lays the groundwork for the eventual subordination, regulation, and domination of all aspects of public and private life.

Another explanation sees a connection between the rise of totalitarianism and the influence exerted by certain traditions in political philosophy that promote a theoretical justification for the creation and preservation of an ideal state. Jean-Jacques Rousseau’s concept of a “general will” and G. W. F. Hegel’s exposition of “absolute spirit” in the state are often included in a larger historical narrative that isolates the origins of totalitarianism in the Enlightenment philosophers’ equation of reason with the transformative powers of technology. An alternative explanation views the rise of totalitarianism as part and parcel of European imperialism and racism.

Totalitarianism differs from its equally nondemocratic and modern counterpart, authoritarianism. Whereas the former is concerned with revolutionizing the entirety of social relations, the latter is principally concerned only with exercising and maintaining direct political control. Authoritarian states do not reach into the private sphere, at least to the same extent as their totalitarian counterparts. Authoritarian states thus allow elements of civil society such as religious organizations, schools, private nonpolitical associations, and the press to retain a relative degree of autonomy. Seeking above all to ensure their own political survival, authoritarian states have neither the will nor the resources to control all aspects of social, economic, and individual life. It should be noted, however, that the theoretical distinction between these two kinds of states tends to falter when applied to actual countries. However, the inadequacy of the distinction in this context does often serve to illuminate the extent to which its use is primarily determined by the political perspective of the analyst. For example, during the cold war, conservative commentators were likely to see left-wing dictatorships as “totalitarian” and their right-wing counterparts as “authoritarian.” Analyses of the right-wing military regimes of South America’s Southern Cone have since questioned this easy demarcation.

HISTORY OF THE CONCEPT

Although the term totalitarian was first coined by the Italian fascist philosopher Giovanni Gentile in 1925, it did not come into widespread use in the social sciences until the 1940s. During this period Hannah Arendt, Carl Friedrich, and Zbigniew Brezinski were primarily responsible for expanding the use of the term so that it could serve as a means of understanding the excessive repression associated with Nazi Germany and Stalinist Russia. During the cold war the concept played a pivotal role in the formation of U.S. containment policy directed toward the Soviet Union and other communist and/or socialist states. It then fell into disuse during the 1960s, particularly among Western Sovietologists, either because it was seen as lacking conceptual rigor or, more likely, because it was viewed as more an ideological than an analytical form of typology. Nevertheless, the term was revived a decade later by neoconservative theorist Jeane Kirkpatrick, who sought to influence U.S. foreign policy makers by arguing that although totalitarian states were incapable of transforming themselves into democracies, their authoritarian counterparts could be refashioned into liberal democracies—or at least into nonthreatening realpolitik allies in the U.S. attempt to contain global communism. The appositeness of this argument abruptly expired in the wake of the unanticipated implosions of the Soviet Union and its Eastern bloc allies in the late twentieth century.

In the opening years of the twenty-first century, however, the term was redefined yet again, this time by leftist theorists who pointed to the encroachment of capitalist markets into an increasing number of sectors of liberal democratic states. This growing depoliticization of
Some critics charge that the concept of totalitarianism does not account for the different forms of social totality that may exist, not all of which are tyrannical; that is, that the concept tends to conflate all forms of social totality (the expansion of the public sphere into the private) with statist totality (one where the state controls all aspects of life). However, other forms of social totality, such as communitarianism (in which individuals tend to see in the public realm the fulfillment of their private interests) and involuntary totality (one where pluralistic compromise requires public power to seep into the private realm, such as with the modern welfare state), enjoy widespread support. The conceptual weakness of the concept of totalitarianism lies in its reliance on the abstract liberal democratic bifurcation of society into public and private spheres, an analytical division that seems to grow less rather than more distinct when submitted to historical and theoretical scrutiny.

The concept of totalitarianism has also been faulted for overstating the monolithic nature of the regimes it explains. According to such critics, totalitarian states are more likely to resemble a “fragmented authoritarianism,” where power is dispersed pluralistically among competing elites situated at various levels of government, instead of being derived from any single and totalizing source or idea. Viewed in this manner, totalitarianism no longer functions as an accurate or adequate tool to explain nondemocratic regimes. Some critics have also noted that the term readily lends itself to certain ideological and propagandistic programs; according to one argument, the concept of totalitarianism functions in liberal democratic societies as a way of preempting any theory or practice aimed at an egalitarian transformation of social and political relations. Known as the “blackmail of totalitarianism,” this tactic holds that any achievements associated with a sociopolitical movement with aspirations for expanding equality would inevitably usher in a new reign of terror. Critics note that this “blackmail” attempts to limit the very possibility of egalitarian politics by isolating it as antidemocratic.

Other scholarship also has called into question the traditional juxtaposition of totalitarianism to constitutional democracy. The latter limits the power and authority of the state in order to promote pluralism, whereas the former obliterates the distinction between the state and civil society in order to consolidate its power. However, upon closer inspection, certain similarities between totalitarianism and modern mass democracy are discernible. In both, the state possesses a monopoly of military and police force. Both control certain forms of mass communication and suppress dissent, particularly in times of crisis. Some theorists have noticed that by the early twenty-first century, democracies, not unlike their totalitarian counterparts, have invoked with increasing frequency the state of emergency as a means of preserving the legal norm. Also, as noted originally by Alexis de Tocqueville, modern democracies often engender a high level of conformity to repressive and irrational standards of social behavior—a feature also found in totalitarian states. What this suggests is that, in its own way, the modern mass democracy may be just as adept as totalitarianism at placing effective limits on individual freedom. In this sense, democracy and totalitarianism share certain features that have become hallmarks of a technically advanced mass society.

**TOTALITARIANISM IN POPULAR CULTURE**

By means of literature and cinema, totalitarianism has made its way into the popular imagination. An entire literary genre known as dystopian literature is dedicated to nightmarish representations of totalitarian systems. These depictions are crafted largely through the satirizing of certain trends in contemporary society. The major texts of this genre include Yevgeny Zamyatin’s *We* (1922), Aldous Huxley’s *Brave New World* (1931), and George Orwell’s *1984* (1949). These three works vary in their views as to what elements in contemporary society are most totalitarian. Zamyatin criticizes the desire for technological efficiency and routine rooted in industrial societies by depicting the world as a single state dedicated to the static mathematical and technological routinization of all life. Huxley’s novel targets the fetish of youth, the dangers of consumerism, and the manipulations of the human psyche built into commercial societies, especially the United States. Orwell’s 1984 most directly targets Stalinist totalitarianism, but also includes satirical references to British capitalism. Orwell’s novel is the most controversial of the three works, largely because of its mobilization during the cold war as a political attack on all utopian visions. Cinematic representations of totalitarianism include Bernardo Bertolucci’s *Il Conformista* (*The Conformist*, 1970), Ridley Scott’s *Blade Runner* (1982), and Terry Gilliam’s *Brazil* (1985). Whereas Bertolucci and Gilliam, in quite different ways, tackle totalitarianism from the perspective of the individual’s longing for escape, Scott depicts the loss of humanity in a world dominated politically by large, manipulative corporate interests. Cinematic representations of totalitarianism share the diversity and nightmarish elements of their literary cousins.

TOTEMISM

Totemism has been the subject of much discussion within the social sciences, in particular within the discipline of social anthropology, concerning both what totemism means and whether it is a valid, cross-culturally descriptive term for the range of phenomena it is often used to describe. Various definitions of totemism exist, but it is usually agreed that the word totem is derived from the language of the Ojibwa, an Algonquin Native American ethnic group from north of the Great Lakes region in North America. Claude Lévi-Strauss, who has produced one of the most important works on the subject, Totemism (1962), describes how the Ojibwa expression oototeman means, approximately, “He (she) is a relative of mine” ([1962] 1991, p. 18). This is significant, for a useful and broad definition of totemism is that it refers to the use of plants or animals by social groups as guardians or emblems that are ritually celebrated. In such a system, different social groups are identified with different species.

There have been two phases in how totemism has been considered by anthropologists. Initially, it was presented by such scholars as Émile Durkheim (1858–1917) and James Frazer (1854–1941) within an evolutionary framework—that is, totemism was seen as a unified and universal phenomenon that was a required state of the religious belief through which all societies must proceed. The second, less simplistic view allows for variety in both the classificatory systems and the symbolism evident in totemism in different cultural contexts. The latter is best represented by the work of Lévi-Strauss. A third phase of thinking about totemism is sometimes apparent, that in totemism is at times now subsumed, usually erroneously, within the category of shamanism. As a result, the religious beliefs and practices of hunter-gatherer communities, for instance, might be referred to exclusively as those of shamanism, while totemism is suppressed or avoided. This third view might reflect the fads to which scholarship, like many other endeavors, is subject, for shamanism is academically fashionable at present, whereas totemism is not.

The archaeologist Steven Mithen has suggested that cognitive developments indicate that totemism and anthropomorphic thought developed as early as circa 100,000 years ago as a result of the integration of the domains of social and natural history intelligence (1996). This view is interesting, if difficult to prove, and the denotations of the earliest possible material indicators of totemism have been subject to debate. For example, recent interpreters of Upper Paleolithic rock art, which appeared around 40,000 years ago in Europe, see it as primarily shamanic rather than totemic. This interpretation is based upon the distribution of the images present in rock art. The species represented in a shamanic system will be widely depicted as guardians available to people in many different groups. In contrast, the species represented in totemic rock art are much more preferentially depicted within the group territory for which they serve as a totemic emblem. The later rock art of parts of Australia is usually described as totemic. The rock art of Wardaman country in the Northern Territory, for example, is linked with the “dreaming” (i.e., creation) and with totemism through the representation of painted dreaming beings such as emus, devil dogs, flying foxes, and nail-tail wallabies.

Bruno David has described the central role of totemism in various Australian aboriginal societies, as manifest in rock art but also in totemic centers and sacred objects, and their associated rituals, the whole creating “a socially meaningful, ordered world” (David 2002, p. 51). In the Australian examples, totemism is manifest across whole landscapes; in other societies, it may be prominently attested in different ways. The totem poles produced by various Native North American ethnic groups of the Pacific Northwest Coast, such as the Haida people of the Queen Charlotte Islands, provide an example of the variety that exists, affirming Lévi-Strauss’s thesis, as well as the absence of a universal totemic “template.” Totemism certainly continues today, in Australia and also among the Tallensi of northern Ghana, but as is usual, it forms one element of a set of religious beliefs and practices that cannot be defined as solely totemic. In fact, totemism has probably never been the sole element of any group religious practice and belief where totemism is found, but rather coexists alongside, for instance, animistic beliefs,
ancestral and earth cults, or shamanism. Among New Age groups where paganism, neoshamanism, and druidism are found, totemic beliefs, as understood by the definition given above, apparently do not exist. In the United Kingdom, for instance, where druidism, paganism, and neoshamanism all prevail, totemism rarely enters the relevant vocabulary, perhaps indicating its absence or a need to refine the definition of what totemism is.

TOURISM
Tourism is a complex phenomenon that can be conceptualized on several levels. It can be considered demographically, as the flow of temporary leisure migration across international boundaries (international tourism) or within the boundaries of a given country (domestic tourism). It can be thought of institutionally, as the system of enterprises (airlines, travel companies, touring agencies, hotels, resorts, guest houses, souvenir shops, restaurants, theme parks, and so on) and organizations (travel associations, local and national tourist authorities, and international tourist organizations) that process and serve that flow. Finally, it can be conceptualized socially, as the complex of attitudes, motivations, norms, and role models that regulate and shape that flow into a distinct institutional domain.

Traveling for leisure was common in many historical and premodern societies. Tourism as a socially recognized, separate institutional domain, however, emerged in western Europe only in the course of the nineteenth century.

HISTORY
There have been two major precursors of modern tourism: (1) pilgrimages to sacred places, which created basic services for travelers, such as hostels, and formed routes that prefigured the itineraries of modern sightseeing tourism; (2) spas, or thermal springs, at which members of the European higher classes assembled to “take the waters,” which prefigured popular modern vacationing tourism on seaside beaches.

The Grand Tour of the British nobility and upper classes between the late sixteenth and the early nineteenth centuries was a form of secular pilgrimage to the centers of European antiquity and culture. In its course, an expanding core of major attractions and amenities developed, which constituted the basis of the emergent modern tourist system.

The development of modern tourism was made possible by major technological innovations in transportation, such as the steamship and the train, and later the car and the airplane, which facilitated the establishment of regular transportation services for large numbers of people. The demand for tourist services, however, was provoked by the economic and social changes that followed the Industrial Revolution: Industrial pollution and urbanization separated people from as yet unspoiled nature; the strains of modern life created demands for rest and recreation; secularization and imperial conquests led to a broadened outlook on the world and a growing interest in remote lands and people. The prosperous middle classes increasingly disposed of discretionary income, which enabled them to bear the costs of traveling, while the introduction of social benefits, such as paid vacations, enabled ever broader social strata to travel. The introduction by Cook, in 1841, of the package tour, was followed by other innovations in the organization of travel, such as the formation of travel companies and touring agencies, airlines, and hotel chains, which made traveling fast and easy, even for people with limited cultural capital.

The principal expansion of tourism took place in the second part of the twentieth century, and especially from the 1970s onward, with the emergence of mass tourism to popular destinations. Most citizens of affluent Western countries at the end of the century took at least one annual vacation abroad, and many took two or even more. Tourism from the non-Western countries, especially Japan, and, more recently, India and China, expanded at an accelerating rate; experts predict that by 2010, one hundred million Chinese will be traveling abroad.

hundred million Chinese will be traveling abroad.
THE TOURIST INDUSTRY

Contemporary tourism is a massive phenomenon. According to the World Tourism Organization (UNWTO), there were 808 million international tourists in 2005, up from about 25 million in 1950. The scope of domestic tourism cannot be ascertained, but it is estimated to be three or four times larger than that of international tourism, totaling about 2.5 to 3.0 billion people per year.

Tourism is one of the leading components of world trade, accounting for about 6 percent of world exports of goods and services. In 2004 the total expenditures of international tourists amounted to $623 billion, up from about $2 billion in 1951. The great majority of international border crossings remain concentrated in Europe, a phenomenon ensuing partly from the relatively large number and small size of European countries. Six European countries are among the ten leading global destinations. France tops the list, with about 70 million visitors a year.

As of 2006 global tourism is growing at about 4 percent annually, but the rate of its expansion to non-Western destinations is significantly higher than it is in the old European core. This growth manifests a marked heliotropic tendency, a flow of tourists from the cold North to vacationing destinations in the warm South, particularly those around the Mediterranean, Caribbean, South Pacific, and Southeast Asian coasts.

Mass tourism is an important source of significant economic benefits, particularly to less-developed countries, but these are mostly unequally distributed. It has also generated undesirable and sometimes destructive environmental, social, and cultural consequences in popular destinations, which threaten the sustainability of local tourist industries. Small countries, particularly island states, in which tourism became the dominant industry while other sectors of the economy remained underdeveloped, are often utterly dependent on tourism, and thus often exposed to financial risks created by far-away political and economic crises.

In reaction to the problematic consequences of the hegemonic tourist industry, various kinds of “alternative touristisms” have emerged, such as “green” tourism, eco-tourism, low-impact tourism, and “countercultural” tourism, the latter espoused in the ideology—but not necessarily in the practice—of contemporary backpackers. Most of these alternative touristisms, however, have been eventually absorbed by the tourist industry, which has adapted its services to the particular needs and preferences of alternative tourists.

More recently, rather than seeking alternatives to the industry, environmentalists and other concerned individuals have sought to collaborate with the industry to ascertain the sustainability of tourism development projects. They thus hope to prevent the environmental and social ravages that unconcerned and often speculative developments wrought in sensitive sites in the past.

SOCIOLOGICAL APPROACHES TO TOURISM

Sociologists have been slow in realizing the growing significance of tourism. Early commentators tended to disparage rather than analyze the phenomenon. Once its study was initiated, the principal issue of concern became the relationship between tourism and modernity (and, later on, postmodernity). Dean MacCannell (1973) proposed a distinctly sociological perspective on tourism, by conceiving of the tourist as a modern individual who, alienated from his own society, travels in quest of authentic experiences in other places and other times—in pristine nature, unspoiled, simple communities, or the traces of great civilizations of the past. In MacCannell’s view, however, this quest is thwarted by the locals at the destinations, who stage “authentic” tourist settings for the visitors’ consumption.

Though influential as a paradigm for the sociological study of modern tourism, MacCannell’s approach was also much contested. Critics argued that he essentialized “the tourist,” disregarding the empirical variety of touristic phenomena; while a quest for authenticity might be a modern cultural ideal, not all tourists are believed to pursue it to the same extent. Typologies of tourists and touristic experiences were proposed (Cohen 2004). Authenticity was shown to be a socially constructed concept, rather than a given fact. Ning Wang (2000) distinguished between three kinds of authenticity: objective, constructed, and existential—the latter being a state of exalting, “of really living,” virtually independent of the nature of the tourist’s surroundings. Wang’s concept may help explain the attractiveness of otherwise overtly contrived attractions, such as theme parks.

The emerging discourse of postmodern tourism, or the “post-tourist” (Urry 1990), moved away from MacCannell’s paradigm. In a world allegedly devoid of originals, and dominated by simulacra (Baudrillard 1988), the quest for authenticity becomes senseless. The growing interpenetration of cultures in the twin processes of globalization and “glocalization” blurs the distinction between home and away, and between ordinary leisure and tourism. Sophisticated and reflective post-tourists are said to travel in quest of enjoyment of experiences that, while familiar, are of a higher quality, more abundant, more varied (and cheaper) than those available at home. They are particularly attracted to the “world cities,” such as London, Paris, or New York, which are the pacemakers in contemporary music, art, fashions, and cuisine, but they may also derive fun from visits to such contrived attrac-
tions as technologically highly sophisticated theme parks, of which the Disneylands are the prototype. Some researchers argue that the alleged fragmentation of the postmodern worldview, and of individual identities, is reflected in the post-tourists’ tendency to mix diverse experiences on the same trip (Uriely 2005), thus thwarting the possibility of constructing typologies of post-tourists.

In the contemporary world, tourism often merges with other institutional domains, such as education (study tours), religion (pilgrimage-tourism), sports (extreme tourism), and recently even medicine. Medical tourism, combining vacations with medical services, emerged in the last years of the twentieth century as a rapidly expanding phenomenon, with growing numbers of people from developed countries seeking a variety of treatments and checkups in developing ones. They are pushed by the escalating costs of private medicine, and the lengthening of waiting lists for socialized medical services, in their countries of origin, and attracted by the high quality and relatively low costs of treatments offered by top hospitals in several developing countries, such as Brazil, India, Malaysia, Singapore, Thailand, and Turkey. Popular vacationing destinations, such as the islands of southern Thailand, offer package tours, combining vacations with medical checkups, cosmetic treatments, and even surgery. The phenomenon has led to an internal brain drain of qualified physicians from local to foreigner-oriented medical establishments, but it has also encouraged some who emigrated to the developed West to return to their home countries.

THE FUTURE OF TOURISM

The alleged homogenization of the world under the impact of globalization is considered by some authorities as a disincentive for tourism; however, tourist numbers are in fact growing annually, and are projected to continue to grow even more strongly in the future, with much of the expected growth coming from newly prosperous non-Western countries. The tourist system has continually expanded into new regions, though large parts of sub-Saharan Africa, Central Asia, the South American interior, and Antarctica remain as yet relatively little penetrated by it. While it will probably yet expand into most of those regions, space is expected to become the new frontier of tourism in the twenty-first century. As yet affordable only to the extraordinarily rich, and facing apparently insurmountable technological, medical, and economic constraints, space tourism might remain restricted to only a few passengers into the foreseeable future; however, the current popularity of simulated space travel and of brief, commercial flights to the edge of space, offered to the general public, attest to a demand for the “real thing.” If such a demand persists, and is no mere fad inspired by novelty, it might provide the incentive for the necessary scientific breakthroughs in the more remote future. Whether and when space travel will become affordable to broad social strata, however, remains an open question.

TOURISM INDUSTRY

Leisure tourism has long been a pursuit of the wealthy, but it is only since the 1980s that the majority of the population has become involved, either as tourists or as workers catering for their needs—a phenomenon that has raised tourism to the position of one of the world’s largest industries. Domestic tourism is estimated to be ten times greater in volume than international tourism, and yet relatively little is known about it; closer attention has been paid to international tourism. With developments in world trade, better means of transport and communications, intensive marketing, rises in disposable income, improvements in political ties, technological advances, and increased leisure time, international tourism has grown rapidly, as is reflected in the global trend of inbound tourist arrivals and receipts. The number of international arrivals rose from 25 million in 1950 to 763 million in 2004, and receipts rose from $2 billion to $623 billion during the same period (World Tourism Organisation 2006).

Globalization has also contributed to the rapid expansion of tourism, via such changes as deregulation of air transport. The growth of charter flights, low-cost airlines, and package-tour holidays provided a major boost to this expansion. International and domestic tourism
combined generate up to 10 percent of the world’s gross domestic product (GDP) and a considerably higher share in many small nations and developing countries.

The tourism product comprises a combination of goods and services supplied by the tourism industry, as well as nonpriced features that motivate tourism, such as natural sites (such as beaches, mountains, and forests), historic sites, and cultural features. The welcome provided to tourists by industry employees and by the local population is also of fundamental importance. The tourism industry includes hospitality (e.g., accommodation, restaurants), transportation (e.g., airlines, car rental), travel facilitation and information (e.g., tour operators, travel agents, tourist information centers), and attractions and entertainment (e.g., heritage sites and theme, national, and wildlife parks). Thus the scope of tourism supply is wide-ranging and influenced by market conditions that affect the environment in which tourism businesses operate.

The market structures within which tourism businesses operate vary from highly competitive (akin to perfect competition) to monopoly. Key features indicating competitive status are the number and size of firms, degree of concentration, entry and exit conditions, pricing strategies, profit levels, product differentiation, cost structures and capacity, and interaction between firms (Sinclair and Stabler 1997). The classification of the supply components is not straightforward; for example, the transport and accommodation sectors are themselves divided into subcategories with different market structures.

The accommodation sector is dominated by large chains (e.g., Cendant Corporation, Bass Hotels, Marriott, Accor, Choice, Hilton), giving the impression of an oligopolistic structure, and each firm’s strategy takes account of the past and predicted future strategies of the others. This sector also encompasses a large number of other establishments with diverse attributes, including hotels, motels, holiday centers, timeshares, and camping facilities, and the diversity of the products that they provide, and a degree of price control, indicate monopolistic competition. In contrast, a highly competitive market structure characterizes the sales of souvenirs and knickknacks by numerous small businesses, including street-based sellers, who have very limited control over the prices they can charge tourists.

Tour operators negotiate deals with hotels, airlines, and other service operators to assemble holiday packages primarily for the mass market, facilitating a link between suppliers and customers. The packages are retailed through travel agents or directly to the customer. In the United Kingdom, the inbound and outbound tour-operator organizations, UK Inbound and ABTA (Association of British Travel Agents), respectively, defend their interests. ABTA had 6,310 travel-agent office members and 1,052 tour-operator office members in 2005, generating a combined turnover of £26 billion. Eighty-five percent of all package holidays sold in the United Kingdom were sold through ABTA members. The four dominant tour operators in the United Kingdom are Thomson, First Choice, My Travel, and Thomas Cook. Large tour operators are primarily linked to the mass market, whereas specialized tour operators that cater for ecotourists, older tourists, and gay and lesbian travelers are growing rapidly. Although the large tour operator market structure is highly concentrated, suggesting an oligopolistic structure, there is relatively easy entry into and exit from the sector, so it has many of the characteristics of a competitive, contestable market. The fact that many tour operators tend to experience low profit margins also indicates a competitive structure. High sales volumes have enabled the large firms to achieve substantial economies of scale and scope, but they are experiencing intense competition from Internet travel sites.

Travel agents are, in effect, retailers providing travel services to customers for commission. Some are linked to tour operators, and others function independently. This intermediary sector has experienced substantial growth. In the United States there has been an almost fivefold increase in agency outlets since the early 1970s. In the early 1990s more than two-thirds were single-office agents, and just one-fifth were branches of multiple firms. This is in contrast with Europe, where single outlets account for no more than one-third of the total, with the major multiples owning just over one-quarter (Sinclair and Stabler 1997). Like the tour operators, travel agents are facing a major challenge from the rapidly growing Web-based companies that sell a wide range of holiday packages over the Internet.

Transport is a crucial factor in the growth of tourism. With the wide range of transport modes (air, rail, car, bus, coach, ferry), the market structure is diverse. Air travel is of key importance in terms of passengers carried and revenue generated. Since the 1960s air travel has grown tremendously, and with technological change the potential for growth has increased further. With deregulation, privatization, low-cost airlines, and globalization, competition in the air industry is fierce, although oligopolistic conditions and domestic monopoly still exist in some long-haul destinations, and airline alliances such as the Star Alliance and One World have facilitated collaboration. The structures of the bus, coach, ferry, and rail sectors are similar to the air sector’s in that they have problems of high capital costs, fixed capacity, peaked demand, and the need for feeder routes to sustain profitable ones.

The source markets for international tourism are concentrated in the industrialized countries of Europe, the
Americas, and Asia and the Pacific. The main tourist-generating countries are in the world’s industrial core: The United States and Germany are the major markets, followed by the United Kingdom, Japan, France, and Italy. With rising levels of disposable income many emerging economies, such as those of Central and Eastern European countries, have shown fast growth in recent decades, and China is becoming a major source market.

Europe remains the most visited of all regions of the world; since the new millennium it has received almost 60 percent of all international tourists and more than half of total tourism receipts. France is the most popular destination visited by tourists worldwide, followed by Spain, the United States, Italy, China, and the United Kingdom. In terms of international tourism receipts, the United States has been the major recipient, accounting for around 12 percent of the total, followed by Spain (8 percent) and France (7 percent).

Outbreaks of disease or political unrest or terrorist attacks have recently hit the tourism industry with some severe and unexpected downturns in demand. Examples include the Gulf War in the early 1990s, the terrorist attacks at Luxor in Egypt in 1997, the Kosovo conflict in 1999, foot-and-mouth disease in the United Kingdom in 2001, the September 11 terrorist attacks in the United States in 2001, and the tsunami in the South Pacific in 2004. All of these events had negative impacts on the number of international tourist arrivals. In 2003 world tourist arrivals were 691 million, compared with 703 million in 2002. Tourist arrivals from the United States fell from a high of 128 million in 2000 to 113 million in 2003. Despite the volatility in demand over the short term, the World Tourism Organization forecasts that international arrivals will reach more than 1.56 billion by the year 2020, with Europe being the top destination, followed by East Asia and the Pacific, the Americas, Africa and the Middle East, and South Asia.

The recent high growth in tourist arrivals and expenditures affects host destinations in various ways, contributing to higher exports of services, bringing in foreign currency, increasing the level of income, and generating tax revenue. Tourism also generates large numbers of jobs, although remuneration in many parts of the tourist industry is low compared with other industries. There is significant gender structuring in employment. For example, in the United Kingdom in 1995, 76 percent of jobs in the transport sector were filled by men, whereas 62 percent of those in accommodation and catering were undertaken by women (Purcell 1997). Furthermore, in the hospitality sector staff often live on premises and are expected to work long and “unsocial” hours. Many receive low pay, and there is a large proportion of young, female, and part-time and casual staff, as well as high staff turnover in many establishments.

Although the tourism industry has great potential for benefiting recipient countries, major criticisms have been leveled at its impact on the environment as well as on social norms and cultures. Construction of resort hotels and theme parks, for instance, has led to significant changes in the environment and some reduction in the biodiversity of native flora and fauna. Damage to coastal areas has been a cause for concern, with construction of marinas and other water-based activities. Other environmental issues relate to noise and air pollution (for example, from aircraft, vehicles, nightclubs) and to water contamination by discharges from hotels, boats, and cruise ships. These pose serious challenges for destination managers.

Industry problems, ranging from increasing competition between destinations to environmental concerns, have encouraged destinations to introduce structural changes and to think about sustainable tourism. Many destinations have stressed the importance of ecotourism. Tourism is a sensitive industry with respect to changes in economic, social, and political conditions, and tourism activities are hampered by disease, political unrest, and climatic changes. A further challenge for the tourism industry is to consider how to integrate tourism into society such that the economic benefits are equitably shared without significantly damaging the environment.

Toussaint-Louverture
1743–1803

Toussaint-Louverture was one of the most important leaders of the Haitian Revolution. He is generally considered...
to be the father of Haitian independence although he did not survive to see Haiti become free, and during his lifetime he claimed to be loyal to France.

Much of Toussaint’s early life is shrouded in mystery. He was probably born in 1743, a slave on the Bréda plantation at Haut-du-Cap near today’s Cap Haitien. There he was known as Toussaint Bréda. He served the plantation as a caretaker of livestock and a coachman, and was obviously a valuable slave who was treated with some consideration by his masters. He was allowed to marry Suzanne Simone before 1776, and they had three children. The estate manager, Antoine Bayon de Libertat, granted him his freedom, probably around 1774. By the 1780s he owned land and slaves and was a small-scale planter. He also served in the colonial militia. Haitian tradition holds that he went to Savannah, Georgia with the French army to fight in the American Revolution.

Toussaint, who knew how to read and write, became secretary to Georges Biassou (d. 1801), one of the early leaders of the slave rebels in Saint-Domingue’s north province shortly after the great uprising of August 1791. He brought military professionalism and ideological and political coherence to the slave rebels’ cause. After Biassou’s death, Toussaint became supreme commander and led his forces to victories over a wide variety of enemies. It was at this time that he took the surname Louverture. He first fought against the French revolutionary government alongside Spanish and French Royalist troops. When in 1794 the government in Paris abolished slavery, Toussaint switched sides, taking a good-sized Spanish force by surprise and wiping it out. Then, he fought British invaders and dissident Haitian rebels before taking control of the entire island by 1801.

As governor-general of the island, he set up a system of required labor service for the former slaves that tried to respect both the human rights of the agricultural laborers and the property rights of the land owners, and to ensure the supply of tropical produce for the French market. But his system was highly unpopular among the former slaves, who did not want to go back to working on sugar plantations after they had fought a terrible war for their freedom. They refused to work, and the Haitian army had difficulty forcing them. Production of sugar remained very low.

This setback led Napoléon Bonaparte (1769–1821), now the supreme leader in France, to decide that Toussaint’s liberty was not worth the price. Napoléon’s wife and brother-in-law both owned property in Haiti and wanted the old system restored, and Napoléon saw the abolition of slavery as one of the excesses of the radical revolutionaries that he was determined to reverse. When he sent an army in 1802 to overthrow Toussaint and restore the old system, Toussaint and a few of his soldiers fought the invaders, but most of his army obeyed Napoléon’s orders. The few resisters put up a tough fight but were finally defeated. Toussaint was arrested and taken to France, where he died in prison. Even as he was breathing his last, his former generals were becoming aware of Napoléon’s plans and plotting a new uprising. Jean-Jacques Dessalines, Toussaint’s lieutenant, led them in a terrible life-or-death struggle and won Haitian liberty on January 1, 1804.

Toussaint-Louverture became a symbol of freedom for blacks throughout the African diaspora. He inspired an 1802 sonnet by William Wordsworth, “To Toussaint Louverture,” which is considered one of the founding documents of English romanticism in literature as well as an inspiration to English abolitionists. He also inspired the African American artist Jacob Lawrence to make a famous series of portraits illustrating moments in Toussaint’s life. Lawrence’s art played a role in the great African American cultural renaissance of the 1930s and also inspired a re-evaluation of Toussaint in modern scholarship. With The Black Jacobins (1938) C. L. R. James attempted to make the Haitian Revolution fit the Marxist category of bourgeois revolution, but Toussaint somehow took over the book and became the idealized tragic hero. Subsequent scholarship refined James’s view, both by illuminating the repressive nature of Toussaint’s regime and by showing that Toussaint was a pre-revolutionary free colored plantation owner (and so more like the bourgeois James had signally failed to paint him as). However, modern scholars and Haitian national tradition still see him as a tragic, perhaps flawed, but essentially heroic figure who deserves to be considered alongside Martin Luther King Jr., Frederick Douglass, and Marcus Garvey as one of the great heroes of black liberation. Toussaint remains the tragic hero of the Haitian Revolution who wanted to make a just, multiracial society in the French empire and ended up inadvertently creating a black American republic, Haiti, which has been a dictatorship for most of its national existence.

TOWNS

Towns have usually accommodated great social diversity, making them places of magnificent human achievements as well as sometimes-violent struggles over resources and power. The words town and city are largely interchangeable, with the former used more in Britain than in the United States, where it is typically reserved for smaller settlements. The names are applied to places with substantial clusters of residents and buildings as well as complex social and economic structures. In some times and places, towns have been independent and self-governing; in others, they have been granted limited self-government.

The earliest towns emerged in the Middle East and are known only from archaeological evidence. Jericho is sometimes identified as the first town, around 7000 BCE, but many scholars believe that the first true towns were those that arose after the development of agriculture, beginning with Sumerian cities such as Ur, around 3000 BCE. At later dates, towns also developed in productive agricultural regions of Egypt, India, China, and Mesoamerica. Early towns were typically ceremonial centers, home to priests, soldiers, and administrators as well as skilled artisans who made luxury goods for members of the ruling class. Often the demand for luxuries stimulated long-distance trade, and some towns became centers of commerce, in which merchants were among the most wealthy and powerful residents. Coastal towns devoted to trade and commerce first flourished around the eastern Mediterranean in the Phoenician and Greek civilizations, which were later conquered by the Roman Empire. After Rome lost control of the Mediterranean around the fifth century CE, and Muslim invaders subsequently conquered much of the region, many Mediterranean towns became important Islamic administrative and commercial centers, whereas Christian Europe became a much more exclusively rural civilization. Although Italian commercial towns such as Venice and Amalfi revived by the tenth century, towns remained marginal to the rural and feudal society of medieval Europe. Partial exceptions were northern Italy and the Low Countries, where commercial towns ruled much of the countryside. These towns and regions dominated the European cultural revival known as the Renaissance, which began in the fourteenth century.

URBANIZATION AND INDUSTRIALIZATION

For several centuries more, Europe, like the rest of the world, remained a place where a tiny percentage of the population lived in towns, and economies as well as political power were rural-based, with the great majority of the population working in subsistence agriculture, producing a small surplus that supported priestly, warrior, and ruling elites. These elites were sometimes based in towns, and here and there cities grew to great size, for example ancient Rome, medieval Baghdad, Tenochtitlan in Mexico, and several Chinese capitals.

A fundamental change in the role of towns came with urbanization—that is, when larger percentages of a region’s or nation’s population came to live in them. This shift coincided with the growth of large-scale industry, beginning in eighteenth-century England and spreading across much of Europe, and beyond, in the nineteenth century. Many towns grew rapidly as rural migrants arrived in search of work in the new factories or in other trades stimulated by urban growth and industrial wealth. Around 1800 London became the first European city with a million inhabitants; a century later, at least eight more had crossed that threshold, and London’s six million made it far larger than any city in history. Outside of Europe, North America experienced the most dramatic nineteenth-century urban growth. The twentieth century, especially its second half, saw rapid urbanization in other regions, notably East Asia. Whereas the world’s population was still 70 percent rural in 1950, sometime around 2007, town dwellers became a majority. By then, twenty cities, most of them in Asia, had at least ten million inhabitants.

In many poor countries, urban growth has been concentrated in a single city, typically the capital, with floods of migrants drawn by rural overpopulation, political turmoil, and the collapse of agricultural or subsistence economies. In one respect this recent phase differs fundamentally from nineteenth-century Europe: This is often urbanization without industrialization. That had been the exception in nineteenth-century Europe, characteristic of only a few of Europe’s poorest cities, such as Naples and Dublin. By the late twentieth century, however, as political and economic turmoil continued to push rural people toward large cities in their home countries or foreign ones, they arrived in places where there were few industrial jobs, and they joined a vast informal sector of intermittent, insecure, and often illegal work. Following a long tradition, these migrants see towns as places of opportunity, but most of them have little chance for security or prosperity.

SOCIAL AND SPATIAL STRUCTURES

From their earliest origins, towns have been associated with complex social structures and a diversity of occupations and roles. Far more than the countryside, towns have usually encompassed extremes of wealth and poverty, with rulers and wealthy merchants living near their slaves, servants, and laborers. As a result, towns have typically been centers of economic dynamism, cultural innovation, and social and political tensions. These urban phenomena have interested social scientists since the eighteenth century, when Adam Smith’s theory of the division of labor explained the great economic potential inherent in the
occupational specialization found in towns. Many liberal theorists following Smith have also contended that towns fostered individual opportunity and individual identities, thus promoting economic growth as well as new doctrines of citizenship and human rights that challenged traditional barriers of caste and status. However, Karl Marx and other socialists (including Vladimir Lenin), observing the concentration of poverty and misery among urban factory workers and casual laborers, predicted that revolutionary change would begin in towns, where oppressed classes would forge bonds of solidarity.

The combination of urban growth and the breakdown of traditional hierarchies has encouraged the urban upper classes to live apart from their poorer neighbors. The modern town has thus been characterized by horizontal segregation, following two basic patterns that have developed in different times and places. In one, the prestigious town center, the traditional site of palaces and shrines, is reserved for the wealthy, and the poor live on the urban edge in suburbs or shantytowns. This arrangement became typical of many European cities (Paris is the best known) as well as former colonial cities in Asia and Latin America. Alternatively, in some places the city center became a stronghold of business and employment, not a prestigious residential district, and the wealthy moved out to suburbs. This pattern emerged in eighteenth-century England and became even more typical of the United States, where premodern urban traditions are scant. By the end of the twentieth century, suburbanization had become increasingly apparent elsewhere, as communications and transportation technology made it easy for elites to live far from their workplaces. The urban core may remain as an office center, but surrounding areas have become poor, even largely abandoned in the case of the most devastated U.S. cities. Many cities in the United States saw rapid change in the decades after World War II (1939–1945), as white working-class residents moved to the suburbs in large numbers, and industrial jobs either followed or left the area entirely. Left behind in the inner cities were concentrations of poverty, unemployment, and minority groups (mainly African Americans), with high crime rates and poor schools continuing to push upwardly mobile residents outward while making life more difficult for those left behind. By the end of the century, similar problems were becoming apparent in major cities of other wealthy countries, such as Britain and France, sometimes in poor suburbs rather than inner cities. At the same time, a countervailing trend has been the “gentrification” that has created or expanded enclaves of wealthy inner-city residents, sometimes dislodging but not necessarily reducing the concentrations of poverty.

TOWNSHIPS

A township is the land formally allocated to hosting the site of a town; the word township legally refers to both residential and industrial sites. Possibly the most famous townships are in South Africa and were a creation of the apartheid system and its predecessor regimes of white rule. Apartheid was formally instituted as state policy in 1948, but dating from the white settlers’ permanent landing at what is now Cape Town in 1652, racial segregation was formal practice. The townships were racially discriminatory in that “black” African, “colored” (mixed-race), and “Indian” people were ordered by the Land Act of 1913 and the Group Areas Act of 1950 to live separately. Even within black townships, ethnic groups were often segregated into separate areas for Zulus, Xhosas, Sothos, and others. These laws existed until the early 1990s, and since then there has been only gradual desegregation of formerly white, colored, and Indian areas.

In the area surrounding Johannesburg, South Africa’s largest metropolis (founded with the discovery of gold in 1886), the best-known townships are Soweto (an acronym for “South Western Townships”) and Alexandra. Others include Bosmont (largely colored), Daveyton, Dipsloot, Duduza, El Dorado Park (colored), Etwatwa, Evaton, Ivory Park, Kagiso, Katlehong, KwaThema, Lenasia (Indian), Orange Farm, Tembisa, Thokoza, Tsakane, Vosloorus, and Watriville. These stretch more than 30 miles (50 kilometers) east–west and north–south, and they fuse into other townships near Pretoria and the Vaal River. The area constitutes a vast peri-urban expanse with more than 10 million residents in Gauteng Province. Of the townships, which together host more than half the population, only Alexandra is relatively well located, and hour-long commutes from the distant townships to work are common.

Townships originated from South Africa’s unique economic requirement for inexpensive migratory labor, and they were managed using brutal policing systems as

Townships

well as British municipal administrative traditions. Debates have raged between social scientists and policy advocates since the 1980s about whether to view townships through the lens of collective consumption (as do Jeffrey J. McCarthy and Daniel P. Smit, following Manuel Castells), the urban accumulation of capital (Patrick Bond, following David Harvey), administrative and spatial power (Jennifer Robinson, following Michel Foucault), or urban efficiency (the Urban Foundation, following the World Bank). Townships also give rise to debates about South African race and class (Harold Wolpe), activist political agency (Mzawele Mayekiso), social history from below (Charles van Onselen), and gender relations (Belinda Bozzoli).

Although Cape Town and Port Elizabeth had townships dating to the early modern era, the first modern, formal townships were in Kimberley, where migrant workers came to work in the mines following the discovery of diamonds in 1867. In these early townships were the infamous hostel systems that typically housed sixteen workers per sleeping room for eleven months of the year, with a one-month break to visit families in the Bantustan homelands. Indigenous black people were lured or often forcibly compelled to move from rural areas through a variety of means common to colonialism: the dispossession of good farmland, the expropriation of livestock, “hut taxes” forcibly paid through labor, periodic wars, and other forms of manipulation. Indian workers brought to the seaport city of Durban in the nineteenth century as indentured labor for the sugar estates gradually migrated to cities.

At the turn of the twentieth century, the South African War—also known as the Boer War—was responsible for uprooting large rural populations, including white Afrikaners (people of Dutch and French origin). After gold was discovered in Johannesburg in 1886, a “poor white problem” emerged in the area during the first three decades of the twentieth century. Housing shortages, sanitation crises, and public health epidemics such as an influenza outbreak fed into racial and moral panics about the proximity of black workers, who lived in the same urban neighborhoods as whites for a time. Water-borne sanitation was first introduced in Johannesburg around 1908, but the disposal of excrement for the entire city occurred close to the black locations.

There followed in 1922 a major labor revolt, the Rand Strike, by white gold miners concerned about the erosion of racial privileges as more black workers came to Johannesburg. (By 1946 blacks had become the majority urban residents.) As white workers and farmers gained increasing influence over government policy, more laws were passed to delineate the white cities from township sites for “temporary sojourners” (i.e., black migrant workers) who lived in urban areas so long as they had a job and a passbook to comply with the Pass Laws.

Real-estate property ownership by blacks was forbidden except in two townships near central Johannesburg that preceded the 1913 Land Act, Alexandra and Sophiatown. The latter, renamed Triumph, was destroyed in the 1950s, and residents were forcibly moved to Soweto. The Public Health Act of 1919 gave local administrative powers in some townships to the Department of Health. The Natives (Urban Areas) Act of 1923 provided for formal township (also known as “location”) planning, and the Slums Act of 1934 provided for urban forced removals.

Townships sprouted across Johannesburg and the other main urban centers—Cape Town, Durban, Pretoria, Port Elizabeth, East London, the Vaal, Bloemfontein, and Pietersburg—as firms sought an unending stream of black workers during the high-growth era of the 1930s through the 1960s. Housing, transportation, and rudimentary health facilities were built by mining companies and other large employers.

In this process, several kinds of divisions endemic to South Africa and southern Africa were exacerbated, including class, race, gender, and rural-urban. In particular, women suffered in rural areas across the region by helping to inexpensively reproduce cheap labor through the Bantustan system and migrant labor. Women in these areas provided the kinds of child care, home schooling, home-based medical aid, and care for the elderly that ordinarily would have been provided by tax-based or benefit-based public and private educational, medical, and pension systems in a normal capitalist labor market. Because the women tended to remain in the rural areas caring for their families and communities, the townships had a much higher proportion of male dwellers, and firms were able to keep wages and employee benefits at inordinately low levels.

There were many important anti-apartheid protests in townships, including the famous 1955 Bus Boycott that required long walks by black workers into white towns. Many protests targeted living conditions. The typical township house was a “matchbox” of 430 square feet (40 square meters) with rudimentary plumbing but, until the 1980s, without electricity.

One reason for the adverse socioeconomic conditions was the inadequate tax base—often just beer-hall revenues—for the administratively distinct black townships. In contrast, black workers labored in white cities where employers paid taxes to white authorities, which offered first world amenities to white residents. In protest, community activists raised the demand, “One city, one tax base!” during the 1980s and insisted on integrated metropolitan authorities, in contrast to those who intended to
maintain geographical segregation using U.S.-style suburban planning techniques.

Although the June 16, 1976, Soweto uprising against Afrikaans language education in the schools was the iconic moment of township protest, the nationwide mass uprisings from 1984 to 1986 and from 1989 to 1993 finally gave rise to South Africa’s democracy, born in 1994. The apartheid-era black councilors chosen by white provincial authorities, especially between 1983 and 1994, were universally considered puppet collaborators, and many were forced to resign by anti-apartheid activists. At the same time, late-apartheid policymakers turned to the World Bank and the pro-business Urban Foundation for central advice on privatization of urban-housing stock and services. Public-housing construction ground to a halt by the early 1980s in black townships.

Even after apartheid was overthrown, however, restrictive macroeconomic conditions and neoliberal microeconomic policies meant that living conditions remained uncomfortable in most black townships. Statistics South Africa released a report in October 2002 confirming that in real terms, the average black household income declined 19 percent from 1995 to 2000 while white household income increased 15 percent. The official measure of unemployment rose from 16 percent in 1995 to 31.5 percent in 2002. Add to that figure frustrated job seekers, and the percentage of unemployed people rose to 43 percent. Moreover, at least 10 million people had their water disconnected for nonpayment, and a similar number experienced disconnection for not paying electricity bills.

The first post-apartheid housing minister, Joe Slovo (1926–1995), adopted World Bank advice that included smaller housing subsidies than were necessary and more reliance upon banks for credit. The policy was to give developers $2,000 per unit, leaving scant funds for good building materials, sound construction, and full services. Ironically, due to such neoliberal policies, the new township housing provided by the government in the early 2000s was half as large and constructed with flimsier materials than during apartheid, was located even farther from jobs and community amenities, and had lower-grade state services, including rare rubbish collection, inhumane sanitation, dirt roads, and inadequate storm-water drainage.

By the early 2000s, there were more protests per person in South Africa than in any other country: more than 5,800 counted in one year by police, mostly in the townships. A new set of urban social movements arose in Durban, Johannesburg, and Cape Town that were reminiscent of the civic associations of the 1980s and 1990s.

TOXIC WASTE

The safe disposal of toxic waste has become a global challenge. Each year, world nations produce 440 million tons of toxic waste. This is a highly conservative estimate, given the clandestine nature of the enterprise and fluid definitions of what constitutes hazardous or toxic waste (the terms are used interchangeably). The U.S. Environmental Protection Agency defines hazardous waste as “a waste with properties that make it dangerous or potentially harmful to human health or the environment” (U.S. Environmental Protection Agency 2006). Hazardous waste can be liquids, solids, contained gases, sludge, by-
products of manufacturing processes, or simply discarded commercial products, like cleaning fluids or pesticides.

An international trade has arisen to transfer toxic waste from developed to developing nations. The United Kingdom exported spent mercury to South Africa throughout the 1990s, which claimed at least three lives at a mercury recycling plant, where mercury is removed from waste sludge for reuse. Similarly, the U.S. chemical firm Holtrachem Manufacturing attempted to export 260,000 pounds of spent mercury waste from its U.S. plant in Maine to India in September 2000. The U.S. government defined the spent mercury as a metal with trade value and exempted it from regulations on waste exports. Pressured by environmental advocacy groups, the Indian government refused the shipment and returned it to the United States.

**LAWRENCE SUMMERS’S MEMO**

Some leaders of global financial institutions have offered economic rationale for trade in toxic waste between developed and developing countries. On December 12, 1991, Lawrence Summers, who served as chief economist at the World Bank, wrote an internal memo that stated the World Bank should "be encouraging more migration of the dirty industries to the LDCs," referring to less developed countries (Vallette 1999). His argument was threefold: First, “a given amount of health impairing pollution should be done in the country with the lowest cost, which will be the country with the lowest wages.” Second, as “under-populated countries in Africa are vastly under-polluted, their air quality is probably vastly inefficiently low compared to Los Angeles or Mexico City.” Third, “the concern over an agent that causes a one in a million change in the odds of prostate [sic] cancer is obviously going to be much higher in a country where people survive to get prostate cancer than in a country where under 5 mortality is 200 per thousand” (Vallette 1999). After the memo became public in February 1992, Brazil’s secretary of the environment, José Lutzenberger, wrote to Summers: “Your reasoning is perfectly logical but totally insane” (Vallette 1999). Lutzenberger was forced from office shortly afterward.

As indicated in Summers’s memo, according to the Trade and Environment Database, poor African nations have served as the dumping ground for toxic hazardous waste materials, i.e. raw sewage, sludge, incinerated ashes, contaminated oils, chemical substances, acids, poisonous solvents ejected by chemical, pharmaceutical and fertilizer producing plants in the industrialized world…. Uncontrolled dumping of toxic wastes in Africa has been traced back to the early 1970s, when reports of clandestine deals between African countries and companies in the United States, France, Germany, the United Kingdom, Switzerland, Italy, and the former U.S.S.R. began surfacing (Trade and Environment Database 1996).

The worst victims of this waste shipment have been the African nations of Benin, Nigeria, and Somalia, which became a tempting target for cost-conscious waste traders. On average, the cost of processing toxic waste is as high as $3,000 per ton in industrialized countries, whereas it drops to $5 per ton in developing countries, according to the Trade and Environment Database. In 1987 the United Nations Environment Programme (UNEP) adopted the Cairo Guidelines and Principles for the Environmentally Sound Management of Hazardous Waste, which require toxic-waste exporters to ensure that disposal sites in waste-importing countries meet the safety requirements of national and international regulations.

**BASEL CONVENTION AND BASEL BAN AMENDMENT**

Two years after the UNEP adopted the Cairo Guidelines, the leaders of 118 governments met in the Swiss town of Basel in 1989 and signed the first-ever global treaty regarding toxic waste, the Basel Convention on the Control of Transboundary Movements of Hazardous Wastes and Their Disposal. As of November 2006, more than 165 countries had ratified it to become international law. The Basel Convention was resented by waste-exporting industries and world governments, however, and they tried to cripple its enforcement. To prevent such efforts, the Basel Convention was amended to ban the trade in toxic waste with immediate effect. In all, 83 countries signed on to the 1995 amendment to the Basel Convention, which is now known as the Basel Ban Amendment. This amendment criminalizes all toxic-waste exports from member nations of the Organization of Economic Cooperation and Development (OECD) to non-OECD countries, even for recycling. According to the Basel Action Network, more than 90 percent of toxic-waste exports from OECD to non-OECD countries were meant for recycling.

Interestingly, the United States, which is the single largest producer of toxic waste, has ratified neither the Basel Convention nor the Basel Ban Amendment. The country’s refusal rests on the argument that U.S. laws effectively regulate toxic-waste exports. It is true that the United States has one of the toughest legal regimes to protect the environment, including the Atomic Energy Act of 1954, the Resource Conservation and Recovery Act of 1976, and the Comprehensive Environmental Response, Compensation, and Liability Act, or Superfund Act, of 1986. These legal regimes, however, ensure safe disposal of...
Tracking in Schools

Toxic waste only within the United States, and their impact is diluted in regulating waste exports outside the country.

Even the Basel Convention and the Basel Ban Amendment are marred by several loopholes that allow the toxic-waste trade to continue. Some nations try to circumvent the ban on toxic-waste exports by resorting to bilateral agreements, which they argue fall outside the purview of the Basel Ban Amendment. Japan, which is the world's second-largest economy after the United States, signed bilateral economic partnership agreements (EPAs) in the early 2000s with Singapore, Malaysia, and the Philippines to evade the ban on toxic-waste exports. These EPAs list hazardous wastes as tariff barriers, which Japan believes need be eliminated. Japan is also using free trade agreements to promote free trade in hazardous wastes. Similarly, some governments and industries attempt to nullify the banned designations of toxic wastes under the Basel Convention under one pretext or another, or define them down to continue toxic-waste exporting. The ultimate enforcers, however, are individual governments that allow waste imports. They can defeat international legislation on toxic-waste trade by being lax in the enforcement of the Basel Ban Amendment for short-term economic gains. A vigorous civic engagement by national and international public interest groups is, therefore, crucial to hold the governments of waste-importing countries to their commitments to halt trade in toxic waste. More important, clean production, minimum waste generation, and waste management within the national limits of waste-producing countries can bring an end to the global trade in toxic waste.

TRACKING IN SCHOOLS

Educational tracking refers to the placement of students into different kinds of educational programs according to a defined criterion of similarity or dissimilarity, such as interest, ability, or achievement. There are various types of tracking in schools, including vocational tracks, college preparatory tracks, honors tracks, and the ability tracks of remedial and gifted and talented. Vocational tracks channel students into classes that develop the skills needed to enter the labor market directly after graduation from secondary school. College preparatory tracks channel students into classes that will prepare them to attend institutions of higher education. College preparatory tracks in American high schools also frequently offer advanced classes that provide opportunities for college credit before graduation. Honors tracks channel students into more rigorous classes for college preparation but also enhance these students' chances of attending the college of their choice by giving them opportunity to achieve honors distinction and a higher class ranking upon graduation. The ability tracks of remedial and gifted and talented channel students into programs of study designed to accommodate unusually low or high aptitudes, respectively.

Critics of tracking argue that the tracking process restricts the educational exposure of students in the lower tracks. The earlier tracking occurs, the greater the educational restrictions. The placement of students into vocational, college preparatory, or honors tracks usually occurs upon entrance to secondary school. Because these tracks significantly affect chances for higher education, the tracks restrict the range of future occupational choices as early as age twelve or thirteen. For students who are tracked according to ability, the impact on educational
exposure and future life opportunities is even greater. Ability tracking into remedial or gifted and talented classes often occurs in the primary school grades. In many ability tracking systems, those in the different tracks are exposed to differential amounts of knowledge. Students in remedial tracks are assumed to be slow learners, so they are exposed to less information within a school year than other students; students in gifted and talented tracks are assumed to be fast learners and so are exposed to more information. The longer students are ability tracked, therefore, the progressively greater are the gaps of knowledge between the tracked students and their peers and the fewer are the chances for remedial students to catch up with their peers. Conversely, the gifted and talented students progressively exceed their peers in knowledge, which increases their scores on standardized achievement tests, thereby enhancing their relative chances in future college placements and college career performance.

A more insidious effect of educational tracking that compounds the problem of differential knowledge is differential development of cognitive abilities by track. College preparatory, honors, and gifted and talented tracks provide greater opportunities to develop the higher-order skills of abstract, critical, and creative thinking. The ability to think and solve problems by abstract principles increases scores on college aptitude tests and contributes to successful performance in college classes. Abstract, critical, and creative thinking also contribute to success in professional careers and to effective decision-making in many areas of life, including consumer and voting choices. Students in remedial tracks, especially, have less opportunity to develop these higher-order thinking skills in a formal educational setting. This not only decreases their chances of college and occupational achievement, it reduces their logical capabilities to make successful life choices.

A profound effect of educational tracking is the labeling of students by track, which produces differential performance expectations and subsequent differences in self-images and behaviors. Children in remedial tracks, especially, are labeled negatively by their school administrators, teachers, peers, and, most significant, themselves. They consequently receive less encouragement to achieve, and their self-esteem is lowered. The latter contributes to a self-fulfilling prophecy in which the students expect to fail, so they do not make the effort necessary to succeed.

Another criticism of ability tracking is that it tends to be involuntary. In many societies, such as Japan, the assignment to a vocational or college preparatory track is based on standardized achievement test scores. Honors eligibility is determined by past academic achievement or scores in standardized achievement tests. Ability tracks are determined by students’ performance on tests designed to measure their academic aptitudes.

Educational track placement is strongly correlated with socioeconomic status and race and ethnicity. Students of higher socioeconomic status are substantially more likely to be placed in college preparatory, honors, and gifted and talented tracks; children of lower socioeconomic status, in vocational and remedial tracks. Black children and, with the exception of Asian minorities, ethnic minorities are more likely to be placed in vocational and remedial tracks. The reasons for these differences are varied. Evidence indicates that school counselors are less likely to encourage lower-class and minority children to choose the college preparatory track. Evidence also suggests that class and minority group differences in cultural and social capital contribute to track placement. Parents of lower income children may be less aware of the importance of and opportunities for their children to pursue a college education. In addition, middle class or upper class students are more likely to be eligible for honors programs because they have parents who are able to help with schoolwork or secure tutors for their children. Perhaps the most pernicious effect of socioeconomic and cultural minority differences, however, is that the purported “ability tests” that determine ability track placement do not actually measure native aptitude but rather cultural exposure or, in the terms of the French sociologist Pierre Bourdieu (1930–2002), cultural capital. Students with less exposure to the majority group culture of the middle or higher classes are likely to score lower on the tests.

The consequences of these educational tracking differences by social class and racial and ethnic minority group status is that lower class and racial and ethnic minority students receive a more restricted education that reduces their level of knowledge, the development of their cognitive potential, and their opportunities to attain a high quality college education. Educational tracking thereby relegates a relatively high proportion of the lower classes and racial and ethnic minorities to lower level occupations. It also creates de facto racial or ethnic segregation within the schools, which in turn breeds false stereotypes and prejudice. Tracking in schools consequently serves to reproduce the socioeconomic and racial and ethnic inequalities that already exist in modern societies.

TRADE

Trade is the exchange of goods between locations. For example, bananas from Honduras exchange for automobiles from the United States. International trade between locations in different nations receives far more attention than does domestic trade because nations discriminate against foreigners with international policies that are contested. For example, in 2005, the U.S. Congress ratified a Central American Free Trade Agreement in a hotly contested vote.

Trade also means the exchange of services of factors of production such as labor and capital. For example, Bangalore call centers provide telemarketing labor to U.S. marketers, while U.S. computer engineers maintain hardware and software in Bangalore. Trade in services is quantitatively important, but the distinction between trade in services and trade in goods is often not important. For many purposes, the distinction between international and intranational trade is similarly irrelevant. This essay uses the term trade to mean international trade in goods, but much of its content also applies to intranational trade in goods and services. The distinction is crucial when international trade policy—discrimination against foreigners— is important. (Domestic trade is affected by domestic policy, but seldom controversially.)

The key questions are: What explains the pattern of trade? Is liberal trade policy a good thing? The household’s answer to the first question is that nations import goods that are unavailable domestically or are cheaper than potential domestic substitutes and export goods that are unavailable or more expensive abroad. There are gains from this exchange, to answer the second question—voluntary transactions must be beneficial or they would not be made, once familiarity acquaints participants with exchange.

Economic analysis embeds the household’s insight in an equilibrium system. Crucially, householders take prices as given in their decisions. When all households together react to a new market opportunity, they will necessarily have an impact on prices. International trade theory provides an answer to what makes a nation’s goods cheaper or more expensive in a world where the act of trade changes prices. It also provides an analysis of the gains from trade in complex, many-household production economies. Since all prices normally will change, some households will gain (for example, owners of property or specific skills in the expanding export sector of the economy) while others will lose (for example, owners of property or specific skills in the contracting import sector). Trade theory shows that the gains to the gainers must ordinarily be larger than the losses to the losers.

The answers convince the vast majority of economists about the desirability of trade, provided some compensation for losers from trade is made. But the explanation of how international trade affects the overall well-being of society is also subtle and sometimes misunderstood by a portion of the general population that tends to oppose liberal trade. Opposition to trade liberalization may also arise from well-informed opponents, including lobbies representing workers and firms that might be harmed by liberalization, as well as persons sympathetic to those workers and firms who are skeptical that fair compensation will be provided.

THE PATTERN OF TRADE

Imports are goods and services purchased by domestic households and firms from firms located in foreign countries. Exports are goods and services sold to foreign households and firms by domestic firms. Imports must be paid for by exports, so the market for a nation’s imports is linked to the market for its exports. The price of imports cannot be isolated from the price of exports. Moreover, exports increase the demand for factors such as labor used to produce them, while imports reduce demand for factors used to produce import substitutes. Thus factor markets at home and abroad are linked through the mechanism of trade. (If exports pay for imports every year, trade is balanced. This simplification does no real harm to the analysis. Unbalanced trade has international borrowing or lending as a counterpart, and in this setting exports must pay for imports over time, in present discounted value terms.)

The balanced trade requirement implies that the relative price of exports, the terms of trade, is equal to the volume of imports divided by the volume of exports. Thus trade determines relative prices and, conversely, relative
prices determine trade. The cause of trade must be sought in relative price differences between countries. Indeed, with frictionless trade (that is, international trade without tariffs, quotas, or other barriers to trade), these must be the price differences that would prevail in the absence of trade (autarky).

Compare the relative price (of, for example, wine in terms of cheese) at home to the same relative price abroad in a prior equilibrium with no trade (autarky) or restricted trade. The country with the lower relative price of wine is said to have a comparative advantage in wine, while the other country has, symmetrically, a comparative advantage in cheese. Trade theory predicts that countries will export the good in which they have the comparative advantage. Krugman and Obstfeld (2005) cite a recent study showing that Japan’s opening to trade in the 1850s reveals data consistent with the prediction.

Comparative-advantage differences between nations are explained in trade theory by differences between countries in either technology or factor supplies. Both are realistic—Canada exports grain because its large endowment of agricultural land makes land relatively cheap, but its better technology also provides an edge relative to land-abundant Ukraine. Notice that the mechanism run by relative price differences implies that economy-wide forces (exchange-rate manipulations, environmental or labor standards) that tend to cause uniform (over goods) national differences in costs will tend to cancel out and have no effect on trade patterns.

Absolute, or “competitive,” advantage should be distinguished carefully from comparative advantage, as the former is the source of much fallacious reasoning. For example, suppose there are two countries considering whether they should trade with each other. Prior to the opening of trade, a naive observer would compare the domestic prices or production costs in the two countries good by good and predict that the country with the lower cost, having an absolute or “competitive” advantage, will export the good. But economic theory establishes that this method fails whenever one country could undersell the other for all goods, since the importer could not pay for the imports by exporting. Instead, prices of goods and factors must change so that in the trade equilibrium each country is competitive in its export industry, in which it has a comparative advantage. In equilibrium, prices must clear markets for all goods and factors in the world economy, and exports must pay for imports.

Differences between countries can arise endogenously from their economic interaction, in contrast to the differences which are given prior to trade in the preceding account of comparative advantage. Differences which arise as a result of trade lead to theories of trade that do not necessarily imply comparative advantage—difference in relative prices in the absence of trade. One theory is based on economies of scale, whereby the wider markets brought by trade will confer a cost advantage on one of the countries. Another theory is based on monopolistic competition, whereby the wider markets brought by trade increase product variety as buyers seek the special characteristics of foreign brands.

GAINS FROM TRADE
There are gains from trade in all these models. Each nation can act through trade policy to take more, leading to destructive trade wars with mutual losses. International institutions such as the World Trade Organization (WTO) act to restrain the destructive tendencies of unilateral action.

Within national economies, some members of a nation must lose from trade. For example, factors of production used intensively in export sectors of the economy tend to gain disproportionately when trade expands, while factors used intensively in import competing sectors tend to lose disproportionately. This gives insight into the widespread political resistance to trade that occasionally erupts into protectionism. National institutions act to redistribute some of the gains (U.S. Trade Adjustment Assistance) or provide temporary relief from losses due to trade (antidumping, escape- clause protection). In equilibrium the gains must outweigh the losses; there are gains from trade on average. On the way to equilibrium, it is theoretically possible that losses may temporarily exceed gains, justifying temporary relief measures. Extensive investigation of U.S. cases suggests that losses from trade are small and of short duration and are swamped by the gains from trade.

Most professional economists support liberal trade because there must be gains on average. The average is a “typical” household. Suppose that in autarky equilibrium, the home (domestic) typical household is willing to swap 2 units of cheese for 1 unit of wine. That is, he would be indifferent to moving his consumption and production a small distance to offer the market 2 cheese for 1 wine or 1 wine for 2 cheese. Suppose that a typical foreign country household in the autarky equilibrium is willing to swap 2 wine for 1 cheese. Now allow frictionless trade, and suppose that the new equilibrium price is equal to 1. Each home household offers cheese to foreign households. Formerly it cost 2 cheese for 1 wine, but now the 2 cheese will procure 2 wine, a gain from trade. Similarly, each foreign household can obtain 2 cheese for 2 wine, where formerly this would procure only 1 wine. Both households gain from trade.

What if losers are not compensated? A person must decide for or against liberal trade by weighing individual gains and losses. Ethical considerations give more weight
to the poor. The case for liberal trade is strengthened because the illiberal trade policies of rich countries hurt the poor disproportionately, as documented by Edward Gresser (2002). Poor countries have comparative advantage based on cheap low-skilled labor, hence discrimination against their exports harms the poor citizens of poor countries. At home in rich countries, protection makes food and clothing more expensive, a regressive tax on poor consumers. Among the poor, losers from protection surely outweigh gainers.

Much opposition to liberal trade is based on confusion and ignorance. The confusion of absolute advantage with a valid theory of trade sows fear that a nation must protect itself from overwhelming competition. Ignorance of the harm done to the world’s poor by protection persuades many who favor income redistribution in rich countries to support protection of rich country import-competing workers, who tend to be relatively poor.

TRADE, ANGLO-PORTUGUESE

Anglo-Portuguese trade figures prominently in seventeenth- and eighteenth-century economic literature because it was a central linkage in the Portugal–England–Americas triangular trade, which raised monetary issues ranging from workings of exchange rates and the balance of payments to the effects of money changes on domestic output. These issues overlap with the perennially relevant and wide-ranging questions of how slavery, trade, and European expansion contributed to economic growth and the Industrial Revolution.

England supported the Brazanga (or Bragança) house after the Duke of Bragança staged a palace coup and took the throne as João IV. Commercial-diplomatic relations evolved within the context of successive Anglo-Dutch and Anglo-French conflicts. England’s trade with Portugal was largely an indirect trade with Brazil, which increased considerably in the late seventeenth century as exports of Brazilian sugar were augmented by gold from Minas Gerais and Portuguese fortified wine. In return, England exported light woollens, and at times grain, to Portugal and onwards.

Exempt from Portuguese prohibitions on the export of gold, English naval ships and packet boats carried Portugal’s trade deficit back to London in gold. Richard Cantillon’s “Essay on the Nature of Commerce in General” (in French, 1720s) illustrated the workings of the foreign-exchange market with the London rate of exchange against Portugal and argued that laws against the export of specie raised prices to Portuguese consumers. David Hume’s Political Discourses (1752) reiterated aspects of Cantillon’s position, but also emphasized that imported New World gold had increased output and employment in England.

Adam Smith steered clear of this in The Wealth of Nations (1776). Smith substituted national savings for the balance of trade as a causal factor behind economic growth and harshly criticized the 1703 Methuen Treaty with Portugal. The treaty lowered tariffs on English textiles, ending a brief period in which Portugal had protected manufacturing; in exchange, England guaranteed Portuguese wine a lower tariff than French—a policy Smith portrayed as likely to reduce savings and growth by increasing the cost of wine consumption.

Napoleon’s 1808 invasion led the Portuguese royal house to flee to Brazil and ushered in direct British trade and investment. Nevertheless, David Ricardo famously chose to illustrate the gains from international trade in his Principles of Political Economy (1817) with an exchange of English cloth for Portuguese wine. In his example Ricardo supposed Portugal to be more efficient than England at producing both textiles and wine, but he demonstrated that trade could leave both nations better off—both could have cheaper commodities in greater abundance. Part of this gain would be devoted to savings and capital formation. This aspect of trade ran parallel to Ricardo’s wider argument that British growth was suffering from diminishing returns to capital and labor in agriculture and would revive only if cheap grain were imported. Friedrich List highlighted the asymmetric aspects of this trade pattern in his National System of Political Economy (in German, 1841). In his view, Portugal had allowed itself to become trapped in the production of agricultural goods, whereas England enjoyed continuing technological progress and manufacturing supremacy.

TRADE, BILATERAL

Trade is the exchange of goods or services within market conditions. A synonymous term is commerce, which involves individuals, companies, or even governments and countries when they seek to buy or sell goods and services mainly for profit. Bilateral trade is a form of trade that takes place between two traders or two countries, or two trading blocks, or a trading block and a country.

Initially, people used a bilateral barter system of trade, that is, exchanging goods and services for other goods and services. Money was introduced as a means of exchange as trade developed over time. The development of trade was facilitated and promoted by money, which first took the form of coins and later banknotes, then checks, or bills of exchange, and finally "plastic money" (credit cards). There are many reasons why bilateral trade further expands. As time passes, labor is specialized and divided into discrete activities as people decide to concentrate on the production of a specific good or even a part of a good, and then sell it to purchase other goods. As well, countries differ in comparative advantage for the production and supply of goods or services. On the basis of the theory of comparative advantage proposed by David Ricardo (1817), international free trade is lucrative for all countries.

Comparative advantage (relative cost advantage) as a basis for bilateral trade contrasts with Adam Smith’s absolute advantage (absolute cost advantage), or the proximity effects associated with the gravity model. (The gravity model may predict bilateral trade flows based on distance, economic size, diplomatic relationships, income level, and trade policies between two countries, although the model could be subsumed under relative transportation costs.)

Bilateral trade has evolved through human history. As the most valuable of commodities, metals were a great incentive to trade. The extensive deposits of copper on Cyprus brought the island much wealth from about 3000 BCE. The first extensive trade routes were initially the long rivers (e.g., the Nile, the Tigris), which became the foundation of early civilizations. From the third millennium BCE there is evidence that long-range trade routes existed. The eastern Mediterranean was the first region to develop extensive maritime trade. The presence of Greeks in Mesopotamia and the eastern Mediterranean encouraged a new trade route. Goods were put on board ships after arriving in caravans from Mesopotamia. An ancient trade route existed between China and the Mediterranean Sea linking China with the Roman Empire—the Silk Road, which was not a trade route that existed solely for the purpose of trading in silk; many other commodities were also traded, from gold and ivory to exotic animals and plants. During the Dark Ages (500–1000 CE) trade almost collapsed. The Portuguese expeditions of the fifteenth century brought European ships for the first time into regular contact with sub-Saharan Africa. The Netherlands promoted the free movement of goods, and became the center of free trade in the sixteenth to eighteenth centuries, together with Spain and England. In 1776, the famous economist Adam Smith contributed to trade theory by arguing against mercantilism (that government should protect the economy from international trade through the use of tariffs to achieve a positive trade balance) by pointing out that economic specialization is as advantageous to nations as it is for firms. In 1799, the Dutch East India Company, the world’s largest company at that time, became bankrupt, mainly due to increased competition in free international trade. By the nineteenth century the adoption of free trade was based on absolute advantage until David Ricardo in 1817 demonstrated that all countries can benefit from international trade based on the theory of comparative advantage. In the twentieth century, the Great Depression brought a considerable decrease in trade. The Bretton Woods Agreement, which was signed in 1944 by forty-four countries, aimed at the removal of national trade barriers. In 1947 twenty-three countries made an agreement, the General Agreement on Tariffs and Trade (GATT), to advance free trade. The World Trade Organization (WTO) was formed through the GATT Marrakech Agreement in 1994.

Bilateral trade is a part of each country’s gross domestic product (GDP). A country’s balance of trade is the amount of goods and services that the country exports minus the amount of goods and services that the country imports. The term bilateral trade agreement denotes an agreement on trade issues between two countries or two trading blocks (e.g., the European Union and Mercosur) or a trading block and a country (e.g., the EU and China). The main aim of a bilateral trade agreement is the elimination of barriers in trade and the facilitation of the movement of goods and services across the national or regional
Trade Deficit

borders to encourage expansion and diversification of trade. Other decisive goals of bilateral trade agreements can be the promotion of fair competition conditions; the substantial increase of investment opportunities; the provision of protective measures concerning intellectual property rights; and the creation of procedures that will secure the implementation and application of the bilateral agreement. All the abovementioned goals are achieved by the bilateral jointed administration of the agreement and the removal of disagreements, together with the establishment of a framework that will further trilateral, regional, and multilateral cooperation in order to promote the advantages of the bilateral trade agreement.

Throughout history bilateral trade has been standard practice. However, the importance it carries economically, socially, and politically has increased substantially recently. This is due to industrialization, advanced transportation, globalization, multinational corporations, and outsourcing (Bitzenis 2004). High tariffs, governmental quotas, and restrictions are usually used to regulate bilateral international trade. Although tariffs are usually imposed on imports, it is not unusual for a country with a protectionist policy to impose export tariffs or provide subsidies. Such restrictions are known as trade barriers; free trade exists in a situation where a government does not impose any trade barriers. Countries are sometimes punished economically by other nations through the implementation of trade sanctions against it. The term embargo—that is, externally imposed isolation that is severe—refers to the total absence of trade between the two countries. An example is the United States’s trade embargo on Cuba, which has lasted for more than forty years.

A preferential trade agreement (PTA) may exist between two trading partners in a bilateral trade agreement, creating a preferential trading area. In this case, the two trading partners (the two countries or the two trading blocks, or one trading block and a country) reduce tariffs between each other, but do not necessarily abolish them completely; this is the weakest form of economic integration. States that are not party to the PTA do not usually benefit from such reductions. PTAs may have adverse effects on multilateral trade liberalization. Since the creation of the GATT and its successor, the WTO, 362 regional trade agreements have been reported to the WTO; of these, 211 were in force in mid-2006 (Lamy 2006). Agreements with services provisions are more and more common. Trade provisions in sectors not controlled multilaterally are a part of an increasing number of bilateral agreements. According to a World Bank study, Global Economic Prospects 2006: Economic Implications of Remittances and Migration (2005), the percentage of trade that takes place under preference treatment varies from 15 to 40 percent (Lamy 2006). The situation of trade under preference treatment undermines substantially the principle of the “most-favored nation,” which is one of the cornerstones of the WTO.

TRADE DEFICIT

A trade deficit—that is, a deficit on flows of goods and services in a country’s international balance of payments—occurs when a country imports more than it exports. Because the concept of the trade deficit depends intimately on its two component flows of exports and imports, what motivates these cross-border, that is, international, transactions? If a country buys more than it sells, how does it pay for the excess purchases? Does the concept of the trade deficit give a complete picture of a country’s international relationships and flows?

People and firms trade because they want different things, have different skills and technologies, and earn different amounts of money. People and firms value goods and services differently, depending on their income, tastes, and needs. Countries are the aggregation of individual actions by firms and individuals. So, countries differ from
Trade Deficit

one another in terms of resources (such as land, minerals, and educated workers) and the techniques firms use to produce goods and services (such as how much information technology is used in the factory or office), and in terms of tastes and preferences for products (due to, for example, the presence of immigrants or to level of income). These differences are reflected across countries as differences in costs of production, and in prices for goods and services. Because costs and prices differ across countries, it makes sense for a country to trade some of what it holds less dear and produces most cheaply to people who want it more and for whom production is costly or even impossible. Although this is most obvious in the case of goods, the concept holds as well for services, and it is applicable to rich and poor, large and small countries alike.

When individuals and firms buy and sell from each other, international trade takes place. When a country, which is the aggregated activity of firms and individuals, sells goods and services across its international borders, these are termed exports. When a country buys goods and services from abroad, these are termed imports. A trade deficit occurs when the cost of imports exceeds the value of exports. A trade deficit can be measured either on a bilateral basis—when country A imports more from country B than its exports to country B—or on a global basis—when country A’s total exports to all countries is less than country A’s total imports from all countries.

What factors can lead to a trade deficit, where one country buys more from abroad than it sells? A country growing relatively more rapidly than other countries in the world tends to import more than it exports, particularly if the country tends to consume and invest a lot at home, if the price of imports is low compared to the domestic price of similar products, if the country’s residents and firms have a particular taste for imported products, and if there are few barriers to inhibit the purchase of imports. A rapid pace of domestic consumption and investment tends to draw in goods and services from other countries in order to satisfy domestic demand. A relatively low price of imports compared to domestic goods and services (which may be a consequence of the international exchange value of a country’s currency) makes it cheaper for residents and firms to buy the imported product than a similar one from the home producer. Some countries have large immigrant populations or intricate supply chains of production, which can boost imports, all else being equal (although these also can support more exports). Finally, as trade barriers fall, so do the cost of imported products.

Which of these factors is most important to increasing imports relative to exports depends on the particular country. For the United States, which has run a trade deficit for more than twenty-five years, the most important factor is its relatively faster growth of domestic consumption and investment. For some periods over this time span, the exchange value of the currency has further augmented imports and restrained exports.

If a country systematically buys more than it sells, it has to pay for the excess by selling financial assets of the country, or by borrowing. These financial inflows are one counterpart to the trade flows in the international balance of payments. But international financial flows also take place because investors want to diversify their wealth portfolios, increasing their rate of return and changing the IR risk profile. Just as countries differ in resources, technologies, and tastes (thus generating trade flows), countries differ in offerings of and preferences for risk and return on financial assets. So, not only are countries linked through international trade flows, they also are linked through international flows of financial assets.

Whereas a trade deficit implies that there must be some international financial inflow as a balancing entry in the international accounts, there are also large international flows of financial assets that are independent of the trade flows. For the United States, international capital flows both into and out of the country amount to trillions of dollars each year—far more than the cross-border trade flows. Moreover, even as the country as a whole borrows to finance the trade deficit, the inflow of financial capital generally exceeds the trade deficit, as foreign investors purchase U.S. assets and U.S. investors buy foreign assets.

A trade deficit that persists implies that borrowing also rises, as does foreign ownership of domestic financial assets. How long such a country can, or should, import more than it exports might be a policy concern. If the imports and net borrowing are invested in such a way as to increase the capacity of the economy to produce and therefore repay its international financial obligations, then there are few worries. However, if imports and financial inflows do not so augment the economy’s capacity to produce, then there is less support for more imports and financial inflows. In such a situation, the country’s ability to attract financial inflows is at risk, and economic forces such as a depreciation in the exchange value of the currency or a rise in interest rates in the domestic market work to change the growth in imports and exports and bring the trade deficit back into trade balance.

TRADE SURPLUS

A trade surplus occurs when a country’s trade balance is in surplus, or positive. The trade balance, which is also referred to as net exports, is the difference between the value of a country’s exports of goods (EX) and services to other countries and the value of imports of goods and services from other countries (IM):

\[ TB = EX - IM \]

Thus, the trade balance is in surplus when exports exceed imports.

The trade balance is part of a country’s gross domestic product (GDP), which measures the market value of all final goods and services produced in a country. GDP is equal to the sum of the domestic residents’ absorption, A (which is given by the sum of private consumption, private investment, and government consumption), and net exports, TB. This implies that the trade balance can also be described as the difference between a country’s GDP and its domestic absorption:

\[ TB = GDP - A \]

A country therefore runs a trade surplus when its gross domestic product exceeds its domestic absorption.

From an economic point of view, a trade surplus arises when the demand for a country’s export goods is higher than the country’s demand for import goods from the rest of the world. In the traditional, partial equilibrium view of trade flows, export demand depends positively on the economy’s price competitiveness, approximated by the real exchange rate, which is given by the ratio of the price of foreign goods to domestic goods (in foreign currency), and positively on aggregate demand conditions, which are approximated by foreign income. The idea is that when export goods are relatively cheap (i.e., price competitiveness is high), the demand for them will be higher. And when the income of foreign consumers increases they will also consume more goods, which will also increase the demand for the domestic economy’s export goods. By the same token, a country’s import demand is assumed to depend negatively on its price competitiveness and positively on domestic income. A country’s trade balance would therefore improve when a country experiences an improvement in its price competitiveness via a depreciation of its exchange rate or lower inflation relative to the rest of the world, or when domestic income expands at a slower pace relative to the rest of the world. Whether such developments will give rise to a trade surplus depends, of course, on how pronounced these developments are, on the strength of their effect on export and import demand, and on initial conditions.

Changes in domestic and foreign income and the exchange rate that influence the trade balance are in turn the result of macroeconomic fluctuations, such as monetary policy or government expenditure shocks, which affect domestic and foreign economies. The textbook workhorse model for the analysis of the effects of such shocks is the Mundell-Fleming (MF) model (Mundell 1968; Fleming 1962). The model assumes that prices are fixed in the short run, so that short-run production is demand determined. As a result, shocks to aggregate demand affect aggregate income and the real exchange rate and thereby the trade balance via their effect on export and import demand as well as relative prices. The net effect of macroeconomic shocks on the trade balance in the MF model is not always clear-cut and also depends on the exchange rate regime in place. For a textbook exposition of the Mundell-Fleming model see Paul R. Krugman and Maurice Obstfeld (2006).

The more recent class of models of the so-called “New Open Economy Macroeconomics” (NOEM) also builds on the assumption of short-run price stickiness in the analyses of the effects of macroeconomic shocks on the dynamics of exchange rates, trade balances, and other macroeconomic variables. The NOEM models are based on a microfounded intertemporal optimising model framework (see Obstfeld and Rogoff 1995 and 1996 and for an overview of the NOEM framework Lane, 2001). In this setup, trade balance surpluses (deficits) arise because of consumption smoothing. The trade balance is essentially the buffer that allows a country to insulate consumption from short-run income fluctuations. While the assumption of short-run price rigidity is similar to the fix price assumption in the Mundell-Fleming model, the implications of the NOEM framework can differ substantially. The effect of macroeconomic shocks on the trade balance depends in these models on many factors, like the assumptions made regarding the pricing scheme of export firms, the degree of home bias in consumption, whether shocks have been expected or not, or whether they are expected to be transitory or permanent.
Movements of the trade balance are closely linked to financial flows between countries. This becomes clear when looking at the balance of payments identity. The balance of payments records all of a country’s transactions with countries abroad and is equal to the current account balance (CA) plus the capital account balance (KA) less the change in a country’s net foreign reserves (ΔFR) and is by definition equal to zero:

$$BP = CA + KA - ΔFR = 0$$

The capital account balance records all of a country’s capital transactions with countries abroad (sales and purchases of assets), and the change in foreign reserves is the change in a country’s central bank holding of gold and foreign exchange. The current account balance records all of a country’s current transactions with countries abroad including trade in goods and services and a country’s net factor income from abroad; that is net factor income earned on the return on capital invested abroad and net international income receipts, NFI:

$$CA = TB + NFI.$$  

The previous two equations show that, as part of the current account, the trade balance is an important determinant of a country’s net foreign asset position, because the current account balance is equal to the change in its net foreign asset position, which is given by the change in foreign reserves less the capital account balance.

When a country exports more to the rest of the world than it imports (i.e., the country is a net exporter and runs a trade surplus), it produces more than it consumes and sells this production surplus to the rest of the world. In order to finance the transaction, the country is lending to the rest of the world and, as a consequence, improves its net foreign asset position by accumulating foreign assets or repaying outstanding debts that were received from the rest of the world in earlier periods.

The trade balance is an important determinant of a country’s international solvency. The previous equation illustrates that the sum of a country’s trade surplus and its net international income receipts equal the country’s current account balance. This implies that if a country runs perpetual current account deficits, its net foreign asset position is negative and the country is a net debtor to the rest of the world. Thus, the country must generate trade balance surpluses in order to service its foreign debt obligations. Therefore, the international solvency and creditworthiness of a country depends on its ability to meet its foreign debt obligation by generating trade balance surpluses in the future.

### TRADE-OFFS

Given finite resources and limited productive capacity, economies are inevitably constrained with respect to their production and consumption options, particularly in the short run, and consequently must choose among alternatives. These constraints apply both to private individuals in the allocation of their budgets and to the government in its decisions over the provision and financing of public goods. By choosing to have more of one good, an economic agent must be willing to accept less of something else, thus defining a trade-off between the two alternatives. An important challenge facing economic decision makers is to allocate resources efficiently subject to the constraints imposed by the trade-offs they face.

At the aggregate economy-wide level, the constraints imposed by fully utilized finite resources can be represented by a production possibility curve. In his pioneering 1958 textbook *Economics*, Paul Samuleson described this in terms of the choice between “guns” and “butter.” An economy can have more butter only if it is willing to have fewer guns. The number of guns one forgoes in order to obtain an extra unit of butter is referred to as the “opportunity cost” of an extra unit of butter. Not only is this
trade-off negative, but it is generally assumed to be concave with respect to the origin. This implies that each extra marginal unit of butter requires the economy to forgo increasing quantities of guns and is known as the law of increasing costs. This is a consequence of the economy's factors of production being imperfect substitutes in the production of the two commodities. As resources are increasingly transferred from gun production to butter production, they are increasingly more suited for gun production and less efficient for producing butter.

THE PHILLIPS CURVE

The concept of trade-offs is generic, and some of the most important trade-offs relate to policy making. Among the most celebrated is the so-called Phillips curve, named after the New Zealand economist A. W. Phillips. In 1958 Phillips used British data to find a pronounced negative relationship between the rate of unemployment and the rate of (wage) inflation. This was interpreted as confronting policy makers with a trade-off between inflation and economic activity. Introducing an expansionary fiscal policy to reduce unemployment, according to Phillips, will also raise inflation, forcing the policy makers to choose some combination of these two responses.

In the 1960s and 1970s, as economists scrutinized the unemployment-inflation relationship in more detail, the nature of the trade-off was questioned. First, with rising inflation during that period the Phillips curve appeared to be unstable, shifting out over time. Several authors, most notably Milton Friedman in his 1968 article “The Role of Monetary Policy” and Edmund Phelps in his 1967 article “Money-Wage Dynamics and Labor-Market Equilibrium,” argued that the Phillips curve should be augmented to include anticipated inflation. As a result the trade-off between current inflation and unemployment would still shift out over time as past inflation was increasingly incorporated in anticipated inflation. However, in the absence of “money illusion” (the tendency of people to evaluate their wages in nominal terms rather than in real terms), they argued that the trade-off was only temporary. In the long run expectations will be fully realized, and anticipated inflation will fully reflect actual inflation. Unemployment will converge to the “natural rate” of unemployment, a rate determined by the structural characteristics of the economy and independent of conventional monetary and fiscal policy instruments, so there is no long-run unemployment-inflation trade-off. The “rational expectations” revolution led to an even more drastic conclusion. If economic agents are smart and understand the structure of the economy, they will internalize government policy into their inflationary expectations and thus negate the trade-off even in the short run.

OTHER TYPES OF TRADE-OFFS

In contrast to the static (but possibility shifting) trade-offs associated with the Phillips curve, other trade-offs are fundamentally intertemporal or occur over time. The most basic of these is the relationship between investment and consumption. To increase current investment an economy needs to increase its current savings, and with fixed output this involves giving up current consumption. Over time, as the increase in investment augments the capital stock, the economy's productive capacity is increased, thus increasing future consumption; the trade-off is therefore between current consumption and future consumption. In deciding on the intertemporal allocation of resources, an economic agent needs to weigh the short-run consumption losses against the long-run consumption gains.

By its nature investment is also risky and therefore is associated with another important trade-off, that between risk and return, a crucial element in financial decision making. Assuming agents are risk averse, the riskier an investment the higher its return will need to be to compensate the investor for the additional risk. This trade-off between risk and return is the basis for the pricing of risky assets and is central to the theory of corporate finance.

Trade-offs exist in other dimensions as well. Almost all economic decisions have differential effects on different segments of the economy. Some groups inevitably benefit more than others, who may often be adversely affected. This is particularly true of trade policy. A tariff designed to stimulate an import-competing industry, through its effect on the real exchange rate, will affect other sectors of the economy adversely, again giving rise to a trade-off in benefits, this time across industries. Moreover in the presence of externalities, the social opportunity cost may differ from the private opportunity cost, in which case the social and private trade-offs will diverge.

Finally, some trade-offs are more controversial. Some economists argue that devoting resources to improve environmental standards will harm the productive capacity of the economy, implying a trade-off between economic performance and environmental quality. Others argue precisely the opposite; devoting resources to the environment will stimulate employment, increase the efficiency of the economy's productive inputs, and enhance economic performance, thus denying the presence of any trade-off in this case.

Tradition

A key term in the study of culture, tradition refers most often to the collective customs and knowledge of a group or society. Tradition is a source of basic learning, occurring even before formal education begins and continuing throughout life. Its usual connotation is a social process of “handing down” knowledge from generation to generation, especially by oral and customary means. It therefore is associated with precedent and culturally is linked often to a group’s “heritage,” although unlike referring to history, which suggests a time and place in the past, tradition carries a sense of social and cultural patterns—ways of doing things—that continuously occurred “before.” The term has other meanings as well, referring to the substantive results of this process, such as a story or ritual, a custom given social importance through repeated practice, knowledge whose official source cannot be verified but is held widely, or a concept (i.e., a mode of thought or behavior) characteristic of people generally. Social sciences scholarship may therefore refer to a tradition in a culture as a specific song passed down in a group through time or the tradition of a culture more broadly as a way of thinking and acting.

Culture in the past was a reference to place, often to a language group bounded in space, whereas traditions were more variably social—possibly referring to family, age, and gender—and migratory. In academic circles, tradition is more broadly defined than is culture, as in the use of such terms as Western tradition and Eastern tradition; here tradition is used as a synonym for pattern. Culture, by contrast, is applied to all types of associations as well as bounded groups. The view persists that traditions define a culture, rather than the reverse, and the “science of tradition” in European American intellectual history—whose purpose is to objectify and organize tradition—has been associated with folklore and ethnological studies. As a result, many genres and groups labeled “folk” are often considered “traditional” or “tradition-oriented.”

The reverence commonly afforded to tradition indicates that people follow it, willingly or not, and—significantly for social sciences—may define themselves or their group through its presence. Whether following tradition means unconsciously adhering to a severe form of cultural authority or choosing from a tradition that one finds appropriate can be a cause for dispute among social scientists. Implied in this difference is a questioning of whether tradition forces stability and conformity or fosters change and progress. Inherent in the concept is a duality that is constantly negotiated in society: tradition’s reference on the one hand to precedent (as the source of knowledge and action) and on the other hand to the present (as living practice, often adapted and adjusted for particular needs and conditions).

MODERNITY AND CREATIVITY

For social scientists viewing tradition as providing the cultural authority of precedent, there is often an implication that tradition is a contrast to modernity, the latter characterized by individualism (with free will and choice), mobility, and progress. A tradition-oriented, or folk, society in anthropological and sociological scholarship (e.g., on groups such as the Amish, Japanese, Hutterites, and Bedouins) usually has the characteristics of valuing social interdependence, filial and ancestral piety, communitarian stability, and harmony or “group orientation.” Many folklorists, however, theorize that the role of tradition is essential to everyday life in modern complex societies, often enacted through cued and framed speech, narrative, and custom to express social identities within a mass culture or to provide a sense of control for individuals (e.g., dressing and athletic rituals).

Another duality with tradition has been with creativity, particularly in studies of artistic traditions. It is often assumed that “traditional” or “folk” art means repetition or imitation of precedent by a community, whereas “fine” or “creative” art represents individuality and novelty. The former is viewed as primitive or ordinary, whereas the latter is elite and refined. A modern philosophy of the arts incorporating tradition since the twentieth century considers tradition and creativity as intertwined in the artistic process, viewable in everyday practice as well as expressive culture.

CONTESTED AND NATIONAL TRADITIONS

Rather than use tradition to describe national or hemispheric patterns, many social scientists apply it to minority cultures and small groups. Arguably, national traditions have been categorized as histories, whereas marginal groups have often been described in terms of tradition. In public or political discourse in the United States, tradition may be invoked in proposals for maintaining national or majority “traditional values” or preserving the
sanctity provided by tradition for institutions of the nuclear family and religion in daily life. Debates arose through the late twentieth century and into the twenty-first century over virtues that constituted the basis of U.S. culture. Associations such as the Traditional Values Coalition, Toward Tradition, and Citizens for Traditional Values took on the label of tradition to represent conservative religious groups in lobbying for prayer and religious programming in the schools, prohibitions on gay marriage, public support for parochial institutions, and school voucher programs. Although sounding secular and broad-based, traditional in the organizational titles came to stand for an orthodox morality upholding the centrality of religion in public life. It invoked the merit of traditional to describe national “values” proven worthy by time and by popular usage. The implication by advocates of traditional values is that rapid social change has undermined “mainstream” or national values, while opponents argue for establishment of new or multiple traditions that are culturally relative and legitimate even if they are different from the mainstream. Sometimes the culturally relative keyword of multiculturalism, implying that traditions are created anew in contemporary life, may be set against the concept of culturalism, connoting the stability of values passed from generation to generation. Both views, sometimes stated as sides in a U.S. “culture war,” invoke tradition for social legitimacy.

In other countries facing rapid social change and diversity, tradition has been a publicly contested term for viewing different priorities of building national unity and multicultural community. Modifiers to tradition such as national, ethnic, religious, folk, cultural, family, and local have implied a need to place a feeling of social connectedness, a collective memory, in an identified niche within mass society. In the Netherlands, a society with a tradition of tolerance toward minorities, a rapid rise of ethnic and religious minorities (e.g., Muslims from Turkey and Morocco) starting in the late twentieth century caused social scientists to notice political and cultural responses to define and celebrate Dutch traditions (e.g., Koninginnedag [Queen’s birthday], Sinterklaas or St. Nicholas Day) nationally as a way to mollify fears of losing “Dutchness.” While creating a sense of cultural norming, applications of tradition have also been interpreted in social science as a process of “othering”—characterizing groups and individuals who do not conform. Subcultural difference can also be normed, as can be seen in the common Dutch social scientific attention to regional traditions of speech, architecture, and customs to show a type of cultural diversity, even within a small country.

The way that social scientists approach tradition can vary across national lines. It has often been argued that Japan and the United States, for example, provide contrasting views of tradition. In Japanese scholarship, tradition is associated with the reverence given to ancient customs and myths, the system of intimate group life established in hierarchical village social structures, and the everyday expressions of social relations based on rank and filial piety (e.g., different performances of respect to elders and superiors in bowing and speech). Tradition is considered the basis of a unified society, and the concept of modernization is integrated with tradition (technological progress and mobility while maintaining a group orientation). In the United States, tradition is tied to the recent past and is viewed as more varied, befitting a multicultural country. It is a more malleable, privatized concept, with less force of authority, and indeed is often seen as “threatened” or “nostalgic” in a postmodern society. Tradition in the United States is more often associated with religion than public life, although American social scientists frequently discuss organized efforts to “construct” tradition (e.g., folk revivals, ethnic and social movements, “roots” organizations, nationalistic movements).

ADAPTED AND INVENTED TRADITIONS

A binary has emerged in cross-cultural studies of tradition between the naturalistic associations of genuine/authentic and the artificial connotations of invented/organized. The concept of “invented tradition,” defined by the social historian Eric Hobsbawm as “a set of practices, normally governed by overtly or tacitly accepted rules and of a ritual or symbolic nature, which seek to inculcate certain values and norms of behaviour by repetition, which automatically implies continuity with the past” (Hobsbawm 1983, p. 1), suggests a linkage of organizers/inventors’ motivations for creating practices that invoke tradition and instill senses of the past and of belonging, especially within national contexts concerned with the modern displacement of heritage and community. These invented traditions usually are of recent origin but appear or claim to be old. They also try to construct cultural meanings in the public marketplace, which can be contested, such as the ritual of national founding principles in the American Thanksgiving marked by a twentieth-century reenactment of “Pilgrims’ Progress” celebrating the seventeenth-century settlement of the New World and protested by a simultaneously held “National Day of Mourning” sponsored by Native American groups starting in 1970.

Set against the background of change, tradition’s role in the way people live and view the world commands renewed attention as new forms of communication arise. As industrialization and urbanization supposedly ushered in a “break with tradition” in the twentieth century, in the twenty-first century trends of computerization and globalization raise questions anew about the processes of tradi-
Tragedy of the Commons

BIBLIOGRAPHY

TRAGEDY OF THE COMMONS

In 1968 the ecologist Garrett Hardin (1915–2003) published the article “The Tragedy of the Commons,” in which he argued that the problem raised by population growth had only a moral solution. His use of the word tragedy was meant to emphasize the inevitability of destiny and the remorseless working of things. He used the celebrated example of a pasture open to all to illustrate what he considered to be a problem facing the human race in general.

Suppose that a pasture is used freely by herdsmen owning their cattle privately. Acting rationally and selfishly, each herdsman chooses the size of his herd so as to maximize his private gain. Adding one animal yields a positive component reflecting the proceeds from selling the animal. It also involves a cost: if pasture space is scarce, the additional animal results in overgrazing. However, that cost is shared by all herdsmen and is only minimally felt by the particular decision maker. The tragedy unfolds when all decision makers disregard the costs imposed on others, which leads all the herdsmen to own too many animals. Heavy overgrazing results, and the cattle are underfed and fetch low prices. In this scenario, herdsmen will add to their herd until they derive no benefit from the additional animal. This is called rent dissipation. With free access, the magic of Adam Smith’s (1723–1790) invisible hand does not work.

In “The Economic Theory of a Common Property Resource: The Fishery” (1954), H. Scott Gordon provided a technical analysis of the problem well before Hardin gave it celebrity. Gordon described a situation in which a private fisherman does not benefit from restraining his activity: the fish he leaves in the water is likely to be caught by some other fisherman. As a result, valuable fish stocks are often overfished, and fishermen are often poor. The collapse of the North Atlantic cod fishery at the end of the twentieth century, as well as the collapse of the Chilean anchovy fishery two decades earlier, are just two dramatic examples.

The particular conditions inducing waste and rent dissipation that are typical of the tragedy of the commons arise either progressively when populations increase their pressure on a common-access resource, or more suddenly when a resource is discovered or when some technological breakthrough makes its exploitation easier. This is why some such tragedies appear as historical events. For example, whales were not endangered before the introduction of harpoon guns reduced the cost of catching them at the same time that they had become valuable for uses other than food for Inuit. In the early twentieth century, oil was discovered and exploited in common pools in the United States. This led to overextraction as one operator rushed to exploit a pool before others could deplete it. In “The Simple Economics of Easter Island” (1998), Jim Brander and M. Scott Taylor interpret the rise and collapse of that island’s civilization as an instance of tragedy of the commons. Climate change is another example: emitters of greenhouse gases treat the atmosphere as an open-access resource, not taking into account the costs borne by present and future humans (not to mention other species).

While pervasive, is the tragedy of the commons inevitable, as implied by Hardin? Gordon’s analysis identifies common property as the culprit. Were the fishery controlled by a single owner who decided how much fish should be caught, that single owner would bear the consequences of overfishing privately and would properly weigh such costs against the benefits of higher current catches. The outcome would be Pareto efficient under perfect competition.

There are many examples of private property rights solving the tragedy of the commons. The enclosures episode which witnessed the construction of fences
around previously open-access areas in eighteenth- and nineteenth-century England is a celebrated though disputed example. Coase's theorem indicates that any system of property rights, by defining a framework for bargaining, will solve externality problems provided costs of transactions are negligible. In Governing the Commons (1990), Elinor Ostrom analyzes many instances where societies have devised institutions other than private property and markets to secure or induce efficient resource use.

A simple look at the organization of economic and social life shows many potential tragedies being avoided thanks to property rights or other social rules: We accept that we must pay for food that we buy in a supermarket; most of the time, cars do not get robbed while parked on the street; we do not freely cut trees in forests for firewood.

Yet solutions or improvements are not easy to come by. The creation or enforcement of property rights, whether private or otherwise, may be institutionally or technologically difficult. Ideally, property rights must be designed in such a way that they cause decision makers to act in the interest of society as a whole in the use of the resource. In many situations, this is not possible either because the required information is not available at a reasonable cost, or because it will not be revealed to the regulator by decision makers, or because there is no authority with the power to impose the required behavior. In such cases, Coase's theorem does not apply because transaction costs are not negligible. Yet, stakeholders may be aware of the collective costs associated with the tragedy of the commons. They can try to improve the situation by signing contracts or treaties, sometimes involving cooperation. They will do so with due consideration for their position in the status quo as determined by their power.

TRAIL OF TEARS

Andrew Jackson’s 1828 election as U.S. president presaged congressional approval of the Indian Removal Act, which initiated processes that led in the mid- and late 1830s to the notorious Trail of Tears. Although Jackson justified his actions in compelling relocation of southeastern Indian tribes to plains west of the Mississippi River as “a just, humane, liberal policy,” implementation led to widespread suffering, cruel deprivation, and painful deaths for many. All told, perhaps 60,000 Choctaws, Chickasaws, Cherokees, Creeks, and Seminoles found themselves uprooted from traditional homes; the ordeal experienced by Cherokees stands out as emblematic of the policy’s inhumanity.

Understanding of the Trail of Tears and its impact requires recognition of circumstances then prevalent in the United States and of the targets of Jackson’s policy other than Native Americans. For example, beginning with the 1803 Louisiana Purchase certain national leaders including Thomas Jefferson and, later, John C. Calhoun had argued for relocation as the only “permanent solution” to the “Indian problem.” Controversy greeted such calls, but national policy by the time of the Jackson presidency offered Native Americans a strictly limited number of options: acculturation, relocation, or extermination.

Meanwhile, egalitarian and antislavery tides of the American Revolutionary period had subsided in the wake of profound changes in American life. First, a rising tide of immigration had begun to swell the nation’s northern cities. This created competition for livelihoods between the new arrivals, particularly the Irish, and free blacks at a time when Jackson and his allies courted the white immigrant vote. Extension of the “Cotton Kingdom” in the South coincidentally created huge demands for new lands and slave labor, as well as for enhanced governmental protections for chattel slavery. Further accelerating the processes at play were European intellectuals who formulated supposedly scientific theories regarding race, racial superiority, and racial inferiority. As a result, the nation found itself accepting new racist concepts that countenanced harsh and arbitrary treatment of Indians and black Americans.

Finally, Jackson’s personal experiences contributed to the implementation of racist policy. He repeatedly had invaded Spanish Florida to suppress challenges to southern expansion posed by the defiance of Upper (or Red Stick) Creek warriors and of maroon fighters later called Black Seminoles. His troops had destroyed the Apalachicola River Negro Fort in 1816; battled maroons at the Suwannee River in 1818; and, through the agency of Lower Creek raiders, obliterated the Tampa Bay area sanctuary known as Angola in 1821. Having failed to subdue his nemesis, Jackson aimed early implementation of
the removal policy at Florida. By 1835 his actions led to
the outbreak of the Second Seminole War, the longest
Indian war and, arguably, the largest slave uprising in U.S.
history. As noted by General Thomas Jesup, “[This is] a
negro and not an Indian War.” Eventually, the Black
Seminole accepted western relocation but mostly after
negotiated surrender rather than by military defeat. Thus,
the Trail of Tears saw African Americans, as well as Native
Americans, paying dearly for political and social changes
that had placed the nation on the road to Civil War.

to questions such as these that people ask themselves
about others depend to a great extent on their beliefs
about others’ personal characteristics. In other words, trait
inferences—judgments made about people’s stable under-
lying characteristics, also referred to as stable disposi-
tions—play an important role in interpersonal behavior.
Social and personality psychologists have extensively
investigated the trait inference process.

Research in the 1960s and 1970s started from the
assumption that people make trait inferences both care-
fully and logically. Attribution theory predicted that in
order to infer that a certain man is rude, one would have
to gather information indicating that he is rude to people
in general, is ruder than others, and has consistently
behaved rudely over an extended period. Trait inferences
are sometimes based on systematic thinking of this kind,
but researchers recognized early on that trait inferences are
messier and more biased than that. For example, people
are often motivated to infer that individuals have certain
traits and not others; one would probably more readily
infer that a stranger is untrustworthy than that a good
friend is. In addition, people are very quick to infer that
others’ behaviors are reflections of stable dispositions even
when other obvious explanations exist for those behaviors
(the correspondence bias). To illustrate, a nervous-looking
woman might be perceived as being a generally anxious
person even if she is in a situation that would clearly make
anyone nervous.

People infer traits from others’ behavior so readily
that they often do so unintentionally and without even
being aware of it. In other words, people infer traits effort-
lessly, spontaneously, and automatically when interacting
with others. As a result, one is often unable to bring to
mind any evidence to support one’s beliefs about others’
traits. Unfavorable traits (such as selfishness and unfriend-
liness) are inferred more quickly than favorable ones (such
as generosity and friendliness). The reason for this seems
to be that although favorable behaviors could reflect
favorable traits, they could also have many other causes
(such as a desire to make a good impression on other peo-
ple). Unfavorable behaviors, it is assumed, are more likely
to reflect people’s true underlying natures.

Research conducted since the 1980s, however, indi-
cates that the heavy emphasis on traits as causes of behav-
ior is more characteristic of people in individualistic
cultures (found primarily in North America and western
Europe) than of people in collectivistic cultures (found in
East Asia and South America, among other places). People
in collectivistic cultures are more sensitive to the social
and situational pressures that affect people’s behavior.

Despite all of the biases that creep into the trait infer-
ence process, people’s impressions of others’ traits can still
be very accurate. When researchers ask a number of a per-
son’s acquaintances to make judgments about that person’s
traits, they typically find high levels of agreement.

TRAIT THEORY
Personality traits describe individual differences in human beings’ typical ways of perceiving, thinking, feeling, and behaving that are generally consistent over time and across situations. Three major research areas are central to trait psychology. First, trait psychologists have attempted to identify sets of basic traits that adequately describe between-person variation in human personality. Second, social scientists across disciplines use personality traits to predict behavior and life outcomes. Third, trait psychologists attempt to understand the nature of behavioral consistency and the coherence of the person in relation to situational influences.

DESCRIBING INDIVIDUAL DIFFERENCES: TRAIT STRUCTURE AND HERITABILITY
There are two prominent approaches to identifying the basic personality traits and their organizational structure (McCrae and John 1992). The lexical approach emphasizes the evaluation of personality trait adjectives in the natural language lexicon and assumes that those personality descriptors encoded in everyday language reflect important individual differences, particularly if they are found across languages. The questionnaire approach attempts to assess important traits derived from psychologically based and biologically based personality theories. Self- and peer-ratings on sets of lexically derived or theoretically derived traits have typically been subjected to factor analysis to develop hierarchical organizations of traits reflecting a small number of broad superordinate dimensions overarching a large number of narrow-band traits. At the superordinate level, contemporary trait structural models vary in the number of dimensions necessary to organize lower-order traits, ranging from two to sixteen. Each of these models can be assessed via self- and peer-report using reliable and well-validated questionnaires and rating forms.

In the most influential and widely used structural model, thirty traits are hierarchically organized into five broad bipolar dimensions, reflecting a convergence of the Big Five lexical traits (Goldberg 1990) and the questionnaire-based five-factor model (FFM; Costa and McCrae 1992). The Big Five/FFM dimensions are neuroticism, extraversion, openness, agreeableness, and conscientiousness. Adherents of the Big Five/FFM model assert that these dimensions can be found across languages and personality measures, providing a comprehensive and parsimonious account of individual differences in personality.

Contemporary research on the heritability of traits has focused on the Big Five/FFM dimensions. Behavioral genetic studies have found substantial heritability ranging from 41 percent to 61 percent for the broad dimensions, with little evidence of shared environmental effects (Jang, Livesley, and Vernon 1996). Heritability of the narrow-band traits of the FFM is more modest, ranging from 30 percent to 50 percent. It is widely believed that traits are influenced by multiple genes; molecular genetic studies, however, have not replicated results linking specific genes to personality traits. In addition to the genetic correlates of traits, promising new efforts by neuropsychologists using functional brain imaging and electroencephalogram (EEG) recordings have begun to reveal the neural basis for traits.

PREDICTING BEHAVIOR AND LIFE OUTCOMES
Personality trait theory has been used in almost every branch of social science and practice. Researchers in clinical psychology have effectively used trait theory to predict both symptom-based psychopathology and personality disorders. Trait theories have also been used in treatment planning, as well as for understanding psychotherapy processes and outcomes.

Beyond clinical psychology, trait theory has been applied to industrial/organization psychology where it has been used to predict employee satisfaction and job performance. Personality traits have also been of interest to forensic psychologists in predicting psychopathic and deviant behavior. Other areas in which traits have been successfully employed include: predicting mate selection as well as marital satisfaction, social psychology, counseling, studies of human development across the lifespan, cross-cultural studies, learning and educational outcomes, and health-related behaviors and outcomes.

THE PERSONALITY TRIAD: BEHAVIORAL CONSISTENCY, INDIVIDUAL COHERENCE, AND SITUATIONAL INFLUENCE
Trait theory implies that personality and behavior exhibit levels of temporal stability and cross-situational consistency. There is strong empirical support demonstrating that the rank order of individuals on various trait dimensions is stable (Roberts and DelVecchio 2000), as well as support that individuals’ behavior is relatively consistent across situations (Funder and Colvin 1991). It is also quite evident, however, that situational influences also impact stability and variability of behavior. For many years, the “person–situation debate” generated significant advances in the study of behavioral consistency and variability (Kenrick and Funder 1988), leading to contemporary interactionist models.

Since the early 1990s, evidence has accumulated supporting conceptions of within-person behavioral variability as classes of stable individual differences at the level of
both psychological states and behaviors. While evidence of variability was first interpreted as support of situational influences, contemporary views propose a comfortable coexistence of large within-person variability and large between-person stability in the study of personality (Fleeson 2001; Fleeson and Leicht 2006; Funder 2006). This has recast the person–situuation debate into an effort to integrate personality variability and stability.

These contemporary integrative models involve contextualization of within-person behavioral variability and between-person consistency within the situation and include the cognitive-affective personality system (Mischel and Shoda 1995), knowledge-and-appraisal personality architecture (Cervone 2004), the density distribution of states approach (Fleeson and Leicht 2006), and the latent state-trait theory (Steyer, Schmitt, and Eid 1999). At varying levels of specificity, these models all employ intrapersonal perceptual and meaning-making processes (e.g., explicit cognitive and affective subsystems are often proposed). As suggested by David C. Funder (2006), the future success of such approaches also requires identification of the psychologically salient aspects of situations.

**TRANSACTION COST**

Economists use the term *transaction cost* to refer to costs arising from actions that hinder the ability of two (or more) individuals to achieve mutually desirable objectives or resolve disputes. Originally conceived as the costs of conducting market transactions, recognition that exchange and cooperation also take place within firms (between employers and employees), within legislatures (among politicians trading votes over preferred legislation), and even within families has led to the broadening of the term to include costs incurred in interactions within any institutional or organizational setting.

Transaction costs have been described broadly as “the costs of running the economic system” (Arrow 1970) and have been compared to the frictions that occur in mechanical systems (Williamson 1985, p. 19). Examples include costs arising out of such activities as discovering or communicating opportunities for trade (information, search, and marketing costs), of reaching and describing agreements (bargaining and contracting costs), and of making sure that agreements are honored (monitoring and enforcement costs). The concept also includes costs of litigation (to enforce property rights or contracts or to determine liability for an accident, for example), lobbying (to influence legislation), and the management or administration of firms and government agencies. Although transaction costs are distinguishable from production costs, unnecessary or
excessive production costs incurred to improve one’s bargaining position, or to protect oneself from losses that would result if a trading partner reneged on a deal, are also appropriately regarded as transaction costs.

The logic for focusing on transaction costs derives from an observation by 1991 Nobel laureate Ronald Coase (subsequently dubbed “the Coase theorem”) that, were it not for transaction costs, all possible gains from trade and cooperation would be achieved through voluntary agreements regardless of the particular institutions, legal rules, or organizational forms in place. It follows that if institutions and organizational forms do matter, it must be because transaction costs are significant. And because transaction costs reduce the gains from trade and cooperation available to transactors, institutions and organizational forms that generate lower transaction costs will generally be preferred to alternatives with higher transaction costs.

Early use of transaction costs to explain observed institutional and organizational arrangements were often criticized on the grounds that because transaction costs can be difficult to measure—and cannot be observed at all for institutions and organization forms that are not adopted—claims that observed arrangements minimized transactions costs were easy to make and impossible to refute. If companies are observed producing their own inputs, it must be because the transaction costs of procuring those inputs on the market are too high; if legislators enact strict liability standards for product liability, it must be because a negligence rule would generate excessive transaction costs.

Beginning in the 1970s, economists, led by Oliver Williamson (1985), began to address this criticism by relating the size of transaction costs under different forms of organization to observable characteristics of transactions such as the complexity of the transaction and the degree to which transactions require investments that are “relationship specific,” that is, are designed or located for use in a particular relationship and consequently have a lower value if used for some other purpose. Since then, transaction cost reasoning has been applied to a wide array of organizational forms and institutions. Although its most extensive development has occurred in the analysis of the boundaries of firms and the design of contracts, the theory of transaction costs has also been used to explain the evolution of political institutions and legal rules and the implications of those structures for the economic performance of nations (North, 1991).

TRANSACTION TAXES

Although transaction taxes can be taxes imposed on any transaction, the term generally refers to the taxes imposed on trading of currencies, stocks, and other financial instruments by economists.

One of the most influential transaction tax is the Tobin tax. After the United States’s suspension of convertibility from U.S. dollars to gold and the collapse of the Bretton Woods system in the early 1970s, James Tobin, an economist who later won the Nobel Memorial Prize in Economics in 1981, proposed a charge on all exchange transactions between currencies in all countries. The proposed charge is called the “Tobin tax.” The purpose of the Tobin tax is to discourage short-term speculation in global foreign-exchange markets and thus reduce the exchange-rate volatility, or, in Tobin’s words, “to throw some sand in the wheels of our excessively efficient international money markets” (Tobin 1978, pp. 154–155). Because the Tobin tax is to be levied on all currency-exchange transactions worldwide, it has been suggested that an international organization such as the United Nations, the International Monetary Fund, or the World Bank would manage the Tobin tax, which would be used to stabilize the international economy and promote peace and reduce poverty. Opponents of the Tobin tax argue that such taxes would reduce the liquidity in the exchange markets and actually lead to more volatile exchange rates.

Another type of transaction taxes, securities transaction taxes (STT), has been proposed and implemented in many equity markets. STT are taxes imposed on the trading of stocks, bonds, futures contracts, and option contracts. Unlike the Tobin tax, the implementation of STT does not require international cooperation. Proponents of STT argue that in addition to generating revenues, these taxes may reduce excess volatility. However, opponents argue that the taxes may reduce market liquidity, decrease
market efficiency, and drive trading to other countries. G. William Schwert and Paul Seguin (1993) provided an overview of the costs and benefits of STT. John Campbell and Kenneth Froot (1994) reviewed some international experiences associated with securities transaction taxes and found that the behavioral responses from investors are large in the sense that investors move a significant portion of the trading to markets with lower STT. In the United States, the then House Speaker Jim Wright proposed a “stock transaction tax” in 1987. The 1994 Clinton budget proposal contained a fee of 14 cents for each contract bought and sold on an organized futures exchange. But such taxes have never been passed by Congress. Empirical evidence on the subject has been mixed. Some researchers found that a higher transaction tax leads to a more volatile stock market, contrary to what the proponents claim. The transaction tax can be viewed as part of the transaction costs, which may include broker fees and stamp duty, among other costs associated with trading of stocks, bonds, futures, and options.

**TRANSFER PRICING**

Tax avoidance by multinational companies poses a serious problem for governments. Governments began to grow aware of eroding tax bases as multinational business expanded in the late 1960s. Since tax systems differ from country to country, multinational companies can reduce their tax burden by shifting profits to countries with relatively low tax rates.

Transfer pricing is one method of tax avoidance. A transfer price is a price used for transactions among affiliates. Multinational companies can move income among affiliates located in different countries by manipulating the transfer price used in intrafirm transactions. For example, suppose a parent company in the United States sells goods to a subsidiary in Germany. Suppose also that the corporate tax rate in the United States is higher than the corporate tax rate in Germany. Assuming that a multinational company maximizes joint after-tax profits earned in the two countries, the company reduces its tax payments by using a lower transfer price. A lower transfer price allocates less profit to the United States parent company and more profit to the German subsidiary. The transfer pricing benefits the company via increased after-tax profit. However, the U.S. government suffers a decrease in tax revenue.

Tax avoidance, as outlined above, has also been brought to the public’s attention as an equity issue. Domestic companies are subject to higher effective corporate tax rates when compared to multinational companies. Domestic companies are not able to manipulate their profits, as multinational companies do, for tax-saving purposes.

Corporate tax laws address illegitimate income allocation among a company’s related affiliates. For example, in the United States, Section 482 of the Internal Revenue Code regulates income allocation among affiliates. Many countries employ similar regulations on this type of transaction among affiliates. These regulations require companies to use the so-called arm’s length price for the purpose of filing a tax return. The arm’s length price is defined as the transfer price that would have been used if the intrafirm transaction took place between nonassociated
parties in the market. However, determining the arm’s length price is not straightforward, especially when transactions involve intangibles and services.

In 1991 the Advanced Pricing Agreement (APA) was introduced by the U.S. Internal Revenue Service to resolve disputes associated with determining the arm’s length price. The purpose of the APA is to allow taxpayers and tax authorities to reach a consensus regarding the arm’s length price before taxpayers file a tax return. The APA has been extended to the Bilateral Advanced Pricing Agreement (BAPA), which aims to coordinate the confirmation of the arm’s length price between two countries. The necessity of coordination results from efforts to eliminate international double taxation, which occurs when tax authorities in each jurisdiction apply a different arm’s length price.

Transfer pricing can also occur when transactions between affiliates take place in the same country, though the term usually refers to tax evasion across national borders. The United States has a long history of regulating transfer prices, since transfer price manipulation allows companies to allocate income among affiliates located in different states. Regulation pertaining to interstate transaction dates back to 1928.

The U.S. government has been leading transfer pricing discussions in the Organisation for Economic Co-operation and Development (OECD), an international organization that coordinates tax policies across countries. The OECD has made several proposals for transfer pricing solutions, one being the Model Tax Convention on Income and on Capital. Providing an outline when two countries enter into a tax treaty, the Model is a suggestion and is not legally binding. The first draft was published in 1963, and the committee on fiscal affairs accepted it in 1977. Since then, the contents of the Model have been periodically updated.

Tax legislation for multinational businesses prompted numerous studies as it became one of the critical policy issues presented by economic globalization. The earlier literature of the 1970s and 1980s tried to provide a theoretical framework for the decision making of multinational companies under different tax rates across countries. The literature demonstrated that multinational companies could increase global income by shifting their profits to lower-taxed jurisdictions by transfer price manipulation. While it is clear that the mechanism of transfer pricing can serve as an arbitrage device to reduce the tax burden of companies, these studies treated tax policies as exogenous.

The literature of the 1990s studied policy planning as it applied to a less-informed government that was attempting to regulate tax evasion. Transfer pricing information is private and generally beyond government control. The literature proposed an analysis of mechanism design using a principal-agent model. The question posed was how to implement tax policies that induce appropriate transfer prices from multinational companies.

The policy concern became one of efficiency loss rather than information constraints after the introduction of the APA and BAPA. The literature in the early 2000s argues that the BAPA system causes efficiency losses since multinational companies, while integrated under common control, cannot internalize the costs of intrafirm transactions. The BAPA separates the profits earned by two different affiliates within the same company for the purposes of imposing taxes in each country. Corporate profits (and tax revenue) will, consequently, be lower.

TRANSFORMATION, STRUCTURAL
SEE Structural Transformation.

TRANSFORMATION PROBLEM
The so-called transformation problem has to do with an apparent contradiction between Marx’s labor theory of value and the tendency of profit rates to equalize across industries. The labor theory of value, which assumes that labor is the source of both value and surplus value (or profit), seems to imply that “labor-intensive” industries would have a higher rate of profit than “capital-intensive” industries. Marx claimed to have resolved this apparent contradiction in Part 2 of Volume 3 of Capital with his
theory of prices of production, which may be very briefly summarized as follows:

1. The general rate of profit is determined by the ratio of the total surplus value to the total capital invested in the economy as a whole \( R = S / (C + V) \) (in Volume 1 of *Capital*, the total surplus value is determined by the labor theory of value).

2. The average profit in each industry is determined by the product of the general rate of profit and the capital invested in each industry \( II_i = R(C_i + V_i) \).

3. The price of production for each industry is determined by the sum of the constant capital and variable capital in each industry and the average profit in each industry \( PP_i = C_i + V_i + II_i \).

In this way, Marx claimed, each industry receives the same rate of profit in a way that is consistent with the labor theory of value.

A long-standing criticism of Marx's theory of prices of production is that he "failed to transform the inputs" of constant capital and variable capital from values to prices of production. According to this interpretation, constant capital and variable capital are derived from given physical quantities of means of production and means of subsistence (they are first determined as the values of these groups of commodities in Volume 1, and then determined as their prices of production in Volume 3). The criticism is that Marx failed to make this transformation of constant capital and variable capital in Volume 3, but instead left these inputs in value terms. Marx's theory is therefore logically incomplete and inconsistent: Output prices are prices of production, but input prices are values. It is further argued that Marx's mistake can be corrected, using a method first suggested by Ladislaus von Bortkiewicz in 1905 and popularized by Paul Sweezy in 1942, but this correction has damaging consequences for Marx's theory. This is because Marx's two aggregate equalities (total price of production = total value, and total profit = total surplus value) cannot both be true simultaneously, and because the rate of profit changes (so that the "value rate of profit" \( \equiv \) "price rate of profit"). These results mean that individual prices and profits are not merely the redistribution of aggregate amounts of value and surplus value, as Marx claimed. This alleged logical inconsistency has been the main reason for the rejection of Marx's theory over the last century by mainstream economists and others. The Sraffian interpretation of Marx's theory (Steedman 1977) has reinforced these criticisms.

Most Marxists have largely accepted these criticisms of Marx's theory of prices of production (that he failed to transform the inputs, and that the two aggregate equalities cannot both be true at the same time), although they draw different conclusions. Marxists have generally argued that these are minor problems, requiring only minor modifications, and that they are not sufficient reason to reject Marx's theory, especially when compared to mainstream theories of profit, which have much more serious logical problems and much less explanatory power.

Since the 1980s, there have been several new reinterpretations of the transformation problem that have provided stronger defenses of Marx's theory. The best known and most influential of these new works on the transformation problem is the "new interpretation." It was presented originally, and independently, by Duncan Foley in 1982 and Gerard Duménil in 1983 and 1984. The main innovation of the new interpretation is that it argues that variable capital is not derived from a given quantity of means of subsistence, but is instead taken as given, as the actual quantity of money capital advanced to purchase labor power in the real capitalist economy, and that this is equal to the price of production of the means of subsistence, not the value of the means of subsistence. Furthermore, this same quantity of variable capital is taken both in the theory of value and in the theory of prices of production. In other words, variable capital does not change in the transformation of values into prices of production. It follows from this interpretation of variable capital that total profit is always equal to total surplus value. The new interpretation also redefines the aggregate price equality in terms of the "net price" of commodities, rather than the "gross price," and it assumes that this net-price equality is always true. Therefore, according to the new interpretation, both of Marx's two aggregate equalities, redefined in this way, are always true simultaneously. However, the new interpretation continues to accept the standard interpretation of constant capital, so that constant capital changes in the transformation of values into prices of production, and Marx's gross aggregate price equality is not satisfied (and the rate of profit also changes).

The "macro-monetary" interpretation presented by Fred Moseley in 2000 extends the new interpretation to constant capital as well as variable capital. Moseley argues that both variable capital and constant capital are taken as given, as the actual quantities of money capital advanced to purchase means of production and labor power in the real capitalist economy, and that these are equal to the price of production of the means of subsistence and the means of production, respectively. The crucial point is that these same quantities of constant capital and variable capital are taken as given in both the theory of value and the theory of prices of production. It follows from this interpretation of the initial givens in Marx's theory that both of Marx's two aggregate equalities are always true simultaneously, and also that the rate of profit does not change.
Similar interpretations have been presented by Richard Wolff, Antonio Callari, and Bruce Roberts (1984), and by Andrew Kliman and Ted McGlone (1988), although these interpretations are also different in some respects. It remains to be seen whether these recent reinterpretations will be accepted by the majority of Marxist economists and by the critics of Marx. But a new phase in the long debate has been opened up, which could lead to different conclusions concerning the logical consistency of Marx’s theory.

**TRANSGENDER**

*Transgender* is an umbrella term that describes different ways in which people transgress the gender boundaries that are constituted within a society. Groups encompassed by this term include people who have an atypical gender expression, sex, sexual identity, or gender identity. An understanding of transgender requires an awareness of the difference between the terms sex and gender—terms that often are conflated.

Sex is a biological construct. It refers to a person’s physical anatomy, usually determined by their genetics and exposure to hormones. While sex often is considered dichotomous, so that individuals are classified as male if they have a penis and as female if they have a vagina, intersexed persons are an exception to this dichotomy because they have features of both sexes (Fausto-Sterling 2000). The debate about the treatment of intersexed infants whose sex organs do not appear traditionally male or female has been heated. On one side, people feel that genital surgery should be performed early so that the infant has the genitalia of one sex and can be raised without confusion about their sexual identity—that is, without confusion about how they understand and label their own sex. On the other side, organizations of intersexed people, such as the Intersex Society of North America, have protested this practice on the grounds that the sex assigned to the child in surgery may not correspond with their sexual identity as they mature. Instead, they argue that intersexed children should be raised with their genitalia unaltered until they are old enough to determine if they would like genital surgery and, if so, to select which sex is a better fit for them.

Unlike sex, gender is a social construct. Within social groups, sets of traits are linked together come to form genders, such as masculinity and femininity, through repeated performance and symbolism. The set of traits may depend upon the culture and time, such that enacting femininity in one country may appear different from doing so within another country or within another era. While many cultures recognize two genders attributed to male or female physical sexes, other cultures have formed genders that are based upon a combination of the sexes and personalities of individuals. For instance, some Native American tribes recognized “two-spirit” people as having distinct genders with valued social roles—so “masculine women” might become warriors and “feminine men” healers (Feinberg 1996).

In most cultures, however, gender is thought to be dictated by one’s physical sex, without any recognition of the cultural assignment of gender traits to one sex or another. When people fall outside the norms of gender transgression—that is, enacting traits that are attributed to the other sex—they may fall into one of the categories of transgender identity. People who adopt gender expressions (i.e., appearances that reflect gendered traits) that are not consistent with their sex by wearing clothing that is associated with the other sex may identify as cross-dressers or as transvestites. Because women are permitted a broader range of apparel in the West, male cross-dressers are more common and noticeable than female cross-dressers. Cross-dressing does not indicate a person’s sexual orientation; in fact, most male cross-dressers identify as heterosexual (Docter and Prince 1997).

*Transsexual* people have a sexual identity that does not match their physical sex. While some desire sex-reas-
Transgender

signment surgery so that their anatomy can match their sense of self, not all transsexuals want to change their bodies. Surgery is costly, and can have mixed results. Hormone therapy may be used as well, as a complement to surgery or independently, and is less costly. To receive services, many clinics require that transsexual people first meet the Harry Benjamin Standards of Care (Meyer et al. 2001), which detail a list of steps that people complete to show that they are ready for surgery—such as living for a year as the other sex. Transmen or FTM (female-to-male) and transwomen or MTF (male-to-female) are common labels to describe the sex of those who transition from one sex to the other.

Sexual orientation refers to one’s emotional, physical, and sexual attraction to another person. Individuals who are attracted to the other sex are heterosexual, to the same sex are homosexual, and to both sexes are bisexual. While having a sexual orientation other than heterosexual does not necessitate a transgender sexual identity or gender expression, there are forms of gender or gender expression within some nonheterosexual communities that fall under a transgender rubric. For instance, being in drag is slang that connotes appearing and acting, for entertainment purposes, in a way that is typical for the other sex—with drag queens being men emulating women and drag kings being women emulating men (Volcano and Halberstam 1999). Within lesbian communities, terms like butch and femme describe the gender identities of women who display different sets of gendered traits. Although they often are misunderstood as mimicking heterosexual genders, these genders are composed of traits that do not fall neatly into masculine or feminine genders but have unique meanings within those communities (Levitt and Hiestand 2004).

People who are transgender tend to experience more discrimination and harassment than those who are not, even when compared to gay or lesbian people who are not transgender (Herak 1995; Levitt and Horne 2002). There is debate within the psychological community on how to understand transgender. A diagnosis for gender identity disorder remains listed in the 2000 edition of the Diagnostic and Statistical Manual of Mental Disorders of the American Psychiatric Association. Many mental health professionals believe that this diagnosis should be abolished because it is based upon a false understanding of gender and that treatment should focus on creating supportive environments for transgender youth rather than pathologizing them (Hiestand and Levitt 2005). At the same time, others believe that the diagnosis is necessary so people can obtain insurance coverage for treatments (Brown and Rounsley 1996), and still others persist in conceptualizing transgender as a mental disorder inherent to the individual.

Groups of transgender people have organized to fight for supportive legislation and medical and mental health treatments that meet their needs and respect diversity within gender experiences. Such organizations as the International Foundation for Gender Education and the National Center for Transgender Equality also work to educate the public about transgender issues and concerns.

TRANSNATIONALISM

Although the idea of transnationalism is widely employed in the social sciences to describe long-distance networks, there is little agreement about its precise definition. The concept of transnationalism describes a situation in which nations and communications are connected, regardless of the geographical distances that separate them, typically by new communication technologies that facilitate flows and networks of people, goods, and services. Transnationalism is therefore also associated with such notions as "network society" (Castells 2000) and with international mobility (Urry 2000). Transnationalism can also be used simply as a substitute for the notion of globalization (Held et al. 1999). It is therefore important to distinguish between internationalism and transnationalism. The former refers to cooperation between nation states and encompasses the international relations between governments that are regulated by treaties and agreements. Transnationalism refers to global cooperation between people and can evolve into a global social movement that advocates harmony, multiculturalism, and cosmopolitanism.

Transnationalism is said to be manifest in certain characteristic social phenomena. These include preeminently the global development of ethnic diasporas as a consequence of the international flow of legal and illegal migrants. The growth of such networks of dispersed communities is also associated with the development of transnational crime and with terrorist networks. These cross-border activities involve not just the trade in capitalist goods and services but include drugs, weapons, contraband, and people. The trade in women as prostitutes is part of a larger pattern of global slavery. It is also claimed, primarily in cultural studies, that transnationalism has given rise to new forms of consciousness because migrants have multiple identities and hybrid cultures. The analysis of these global cultural flows is closely associated with the anthropological investigations of Arjun Appadurai (1996, 2001). These fragmented and multiple identities become part of a transnational imaginary that creates fictive communities of membership and belonging. Because these cultural identities and images are drawn from multiple sources, it is claimed by writers such as Homi Bhabha (1994) that many modern cultures are going through a process of hybridization.

Alongside cultural transnationalism, there is the emergence of economic transnationalism, which is manifest in the transnational corporation that produces and sells in global markets beyond the controls of the nation state. There is also, as a result, an international capitalist class that is highly mobile and a transnational working class whose remittances to countries like Pakistan and the Philippines represent a significant contribution to the national economy. These movements of labor now also include large numbers of women, resulting in both the feminization of migrant labor—for example the Filipino maids of Singapore and the Gulf states—and the growth of the transnational marriage (Yeoh et al. 2000). These migratory roots also become the sites of international business communities that can exploit these ethnic ties, however weak and dispersed, to create economic opportunities for global accumulation, as Aihwa Ong (1999) has demonstrated with respect to the diasporic Chinese business community.

Unsurprisingly, transnationalism is thought to have significant political consequences resulting, for example, in the global city as a site of power that can challenge the nation state, or giving rise to a global democracy and a global public sphere (Held 1995) or to new forms of citizenship or “mutations of citizenship” (Ong 2006) and “transnational citizenship” (Bauböck 1994). Transnational migration in creating guest workers and permanent residents has required a reassessment of the relevance of national citizenship to the rights of migrant workers and their families. The legal and political status of migrants as quasi citizens is often ambiguous, because national citizenship is based on both rights and duties. It is often unclear whether migrants, refugees, or asylum seekers should be expected to fulfill the duties of citizens, such as paying taxes or undertaking military service.

Transnationalism is also associated with the idea of cosmopolitanism, and it has been assumed that the porous boundaries of the modern state, along with international cooperation through such institutions as the United Nations, might fulfill Immanuel Kant’s (1724–1804) dream of “perpetual peace” and international harmony (Kant [1795] 1991). However, with growing fear of terrorism after the attack on the World Trade Center in New York in 2001 and the increasing emphasis on domestic and international securitization, many governments are attempting to control the transnational flow of illegal people, goods, and services. One state response is to build walls to contain such flows—for example, between Mexico and the United States. In October 2006 U.S. president George W. Bush signed the Secure Fence Act, which anticipates the creation of a 700-mile barrier to deter illegal migrants. However, walls are also being constructed between Brazil and Paraguay, between Saudi Arabia and Iraq, and between Israel and its Palestinian neighbors. The city council of Padua in Italy has created a steel barrier to divide the respectable side of the city from the high-crime neighborhoods, which are said to be rife with illegal drugs associated with an influx of Nigerian and Tunisian...
migrants. Sociologists have argued therefore that modern states, perceiving transnationalism as a threat to their sovereignty and security, have created an “immobility regime” and that increased surveillance and regulation of populations is resulting in an “enclave society” rather than transnational integration (Turner 2007).

**TRANSPARENCY**

The use of the concept of transparency has become widespread across multiple fields and subfields in the social sciences. In most instances, it is used to describe the ability of one actor to access information from another actor. More simply, transparency can be understood as the opposite of secrecy. “Government transparency” refers to the ability of societal actors to access government-held information. Democratic theory has long emphasized that an accountable, truly democratic polity must make its decisions public to its citizens. Such arguments can be traced as far back as the writings of Jeremy Bentham (1748–1832), who used the concept of “publicity” rather than “transparency,” and James Madison (1751–1836), who argued that “a popular government, without popular information, or the means of acquiring it, is but a prologue to a farce or a tragedy” (Madison 1973, p. 473).

Some authors differentiate between the “openness” of a political system and the transparency of the government. Openness is a reflection of the free flow of information among societal actors (e.g., through a free press). Transparency, on the other hand, reflects the flow of information from governments to society.

The need for government transparency has become part of the broader social science debates on the “principal-agent problem.” Government officials are seen as “agents” who need to act on behalf of citizens (their “principals”). Their actions need to be known and approved by the public. The main opposition to government transparency comes from government bureaucrats, because greater public access to information about bureaucrats’ work increases the likelihood for their mistakes to become visible. Also, lack of transparency sometimes allows government officials to reap “rents” by disclosing information only to individuals friendly to them or their organizations.

Transparency is closely related to the concept of accountability. Accountable governments need first to inform the public of their actions and intentions and, second, to offer mechanisms through which they can be punished for not being representative. Transparency is thus considered a necessary, albeit not sufficient, condition for accountability.

Transparent political systems are considered to be more effective economically and more stable politically; governments that are not transparent are generally more corrupt. Whether corruption is present or not, a secretive political system leads people to assume that government officials have something to hide, so lack of transparency reduces citizens’ faith in the performance of democratic governments and slows down democratic consolidation. Lack of government transparency in many new democracies is one of the factors that can lead to incomplete consolidation or even reversals to authoritarianism.
Transparency is best assured through the adoption of “freedom of information” (FOI) laws. The few existing gauges of government transparency are in fact based on the existence and completeness of such laws. In 1766 Sweden was the first country to adopt freedom of information legislation, as part of its press freedom act. Finland (in the 1950s) and the United States (in the 1960s and 1970s) were the next countries to adopt such laws. In 1990 only fourteen countries had legislation pertaining to citizens’ access to information. From 1991 to 2000, during what Thomas Blanton in “The World’s Right to Know” (2002) called the “decade of transparency,” that number more than doubled. While many of the countries adopting freedom of information laws in the 1990s were new democracies, some consolidated democracies such as the United Kingdom, Italy, and Japan also adopted FOI legislation.

The literature suggests two possible reasons for the increased transparency in the post–cold war era: the emergence of a general “norm of transparency” and technological advances such as the development of personal computers, word processing, photocopying, and, especially, the Internet. Such technologies have led to an increased ability to generate, store, and, more importantly, disseminate information to a large number of citizens. The costs of offering information to the public—one of the long-standing problems associated with government transparency—have been reduced substantially due to such new technologies. But even with the improvements brought by new information technology, many government agencies still struggle with the implementation of freedom of information legislation. In the United States, for example, more than half a million requests for information are made every year under the Freedom of Information Act (FOIA). The FOIA offices that deal with such requests in individual agencies do not have the necessary funds and staff to deal with them, and therefore become backlogged.

Transparency is limited not only because it is costly and time-consuming for government officials, but also because there are limits to the kinds of information that can be made available. Virtually all the countries that allow public access to government information have some restrictions on that access, such as exempting from scrutiny information that endangers national security or individual privacy. Yet a truly transparent government is one that

1. makes clear that access to information is the norm and exemptions are to be resorted to only in exceptional cases;
2. has legislation with precise definitions of the exemptions to the right of access;
3. provides for an independent review of denials of access to information; and
4. requires minimal or no fees for the requested information.

While the literature on transparency still focuses overwhelmingly on the relationship between governments and citizens, the concept is now also used increasingly to describe the ease with which information flows between other types of actors. For example, during international negotiations a state can be characterized as transparent if it offers information about its preferences and intentions to another state; a corporation is transparent when it allows investors access to financial data; an international organization is transparent if states or the public can access information about its workings. This implies that, when discussing transparency, one needs to specify the actor that is offering information and the one who is receiving such information.

The relationship between information and power has long been acknowledged. In the contemporary information age it is only natural that there is a growing interest in who controls information and how they control it. The increased focus on transparency is a reflection of such interests in multiple disciplines in the social sciences.

TRANSPORTATION INDUSTRY
Transportation services move people or freight from one location to another. These services are a near necessity for successful operations of businesses and governments. Efficient transportation systems contribute to businesses fulfilling purchase orders in a timely fashion. They also increase residency options for employees because workers
are not restricted to living in close proximity to their jobs. Government services also benefit from the use of efficient transportation networks by enhancing governments’ ability to respond to national emergencies.

Different modes of transportation are available to satisfy business, government, and commuter demands. Shipping volume and geography dictate the most efficient type of transportation service. For example, trucking, rail, and inland water barges generally transport freight within a country or region. Cost advantages from hauling relatively small shipments of 80,000 pounds or less are associated with trucking carriers primarily because such operations face smaller fixed costs. Often the major source of fixed costs for many trucking carriers is the leasing of trucks. The investment in more trucks and employment of more drivers to meet high volume demand at best is associated with unit costs remaining the same. In contrast, the unit costs of providing shipping service by rail and inland barges declines as volume increases due to large part to the high fixed costs of providing transport. For instance, fixed costs such as the cost of locomotives and barges are substantial and allow for additional freight volume beyond the typical 80,000-pound limit in trucking. Labor costs associated with operating such transport equipment increase less than proportionately with increasing volume given the large hauling capacity of trains and barges.

The shortcoming of trucking, barge, and rail is their inability to provide overseas service. As an alternative, international shippers rely on the services of ocean liners and air carriers. The introduction of containerized shipping by the American entrepreneur Malcom McLean in 1956 contributed to ocean liners’ capacity advantage over aircraft when shipping large quantities of bulk products. In contrast, aircrafts typically transport small packages and parcels. Air transport service also offers the advantage of faster delivery compared to ocean liner service.

Excluding trucking, the major modes of freight transport also provide passenger service. This service constitutes a large share of air transport business. The ability to provide relatively fast transport across long distances makes this mode of travel a superior choice over rail and water passenger service. Light rail service is more cost effective than air transport for service within localities with high population density. Along with bus transport, rail provides an alternative to the use of private automobiles for local commutation. The benefits associated with rail and bus public transit in high-density areas are the easing of traffic congestion and the reduction of pollution emissions. Commuter demand for privacy and scheduling flexibility, however, makes the private use of automobiles a viable option for local commutes.

The economic significance of transportation services is further highlighted by its large share of total national output. For instance, transportation’s share of total trade of commercial export services varies from a low of 16.7 percent in North America to a high of 28.6 percent in Asia, according to World Trade Organization statistics published in 2004. Transportation services’ share of total trade of commercial exports varies from a low of 22.3 percent in Western Europe to a high of 38.5 percent in Africa. The interest of governments in the development of transportation services is universally strong given that these services are a major source of economic growth. Hence, the remainder of this entry explores the twentieth-century history of governments’ influence on the provision of efficient transportation services.

**GOVERNMENT POLICY TOWARD TRANSPORTATION SERVICES**

For the majority of the twentieth century, many countries provided state-owned transportation services. Ownership gave governments the power to offer universal service at affordable rates. Other countries such as the United States imposed economic regulation on private transportation operations. Local U.S. governments’ role in the provision of public transit did resemble that of other countries. Typically U.S. municipalities owned and operated local rail and bus services.

U.S. regulation of transportation services from the 1920s to the mid-1970s restricted carrier competition and set rates along routes. The rationale for limiting competition in rail, air, and water transport was that their high fixed costs made them susceptible to destructive competition. Competition in this type of market leads to periods of carrier foreclosure as firms are unable to cover costs when facing competitive price pressures. Setting the terms for service rates gave rate-makers the opportunity to promote affordable service for a large group of potential customers. Regulation did contribute to reaching policymakers’ goals of avoiding ruinous price competition and providing extensive network service at affordable prices. For example, minimum freight hauling rates were imposed on railroad carriers to help them avoid financial disaster. Entry restrictions, though, required these carriers to service nonlucrative routes to rural agricultural areas. Rate regulation for trucking and airline carriers were set as mark-ups over cost. Market pressure to keep costs low in trucking did not arise since entry restrictions significantly limited entry of potential rivals along routes. Indeed, potential entrants were often limited to offering service to newly formed routes, and even then incumbent carriers were given the initial opportunity to provide such service. This approach toward entry regulation gave established carriers the opportunity to reject servicing potentially
nonlucrative routes. A different regulatory approach was taken for airline carriers as they were required to service low demand locations at the rate charged for high demand locations. Compared to rate regulation in the transportation sectors previously mentioned, ocean liners experienced less government control over rates. Ocean liners were given antitrust immunity in negotiating port-to-port rates for lines involving U.S. foreign commerce.

State-owned operations achieved the goal of providing universal and affordable service by using government revenue to subsidize transit operations. Subsidization of commuter transit was not limited to publicly provided services as commuters using their own motor vehicles drove on roads constructed and maintained with significant financial support from government revenue.

TRANSPORTATION LABOR HISTORY IN A REGULATED BUSINESS ENVIRONMENT

While incumbent transportation carriers, consumers in rural areas, and commuters were the intended beneficiaries of regulation and state ownership, transportation workers also enjoyed significant benefits from these policies. Transportation labor markets became highly unionized following regulatory reform in the early part of the twentieth century. The restriction of competitive entry into transportation services contributed to a large share of these industries’ work forces belonging to a union.

Three years following enactment of the 1935 Motor Carrier Act, the number of trucking employees belonging to the International Brotherhood of Teamsters rose to 370,000 compared to 75,000 in 1933, according to a 1986 report by Charles Perry. Union membership reached 920,000 by 1948. The Teamsters’ membership was concentrated in the highly profitable intercity carriage sector, where 80 percent of workers in that sector belonged to the Teamsters by 1940. Representation of such a large group of workers contributed to the Teamsters ability to negotiate lucrative contracts for its members. Rate regulation that allowed trucking carriers to pass on costs to shippers further contributed to the Teamsters ability to negotiate high wages. Indeed, researchers reveal that union truck drivers received wages 30 to 50 percent above wages paid to nonunion drivers working in less lucrative sectors of the trucking industry.

Union growth in rail, airlines, and ocean shipping differed from trucking. Rather than a single dominant union representing the work force, workers belonged to several unions. Labor law guidelines of the 1926 Railroad Labor Act influenced union development in rail and airlines. This act prohibited rail and airline unions representing different occupational groups of workers employed by the same carrier. Most rail workers belonged to the United Transportation Union, the Brotherhood of Maintenance of Way Employees, and the Transportation Communications Union. Negotiating with several unions presented rail carriers with the opportunity to target the weakest union and use that settlement as a pattern for successful negotiations with other rail carriers. Rail unions addressed this problem in 1973 by collectively negotiating with a group of major carriers. Shifting to group negotiations contributed to union rail workers receiving lucrative contracts.

In contrast to rail, labor relations in the airlines were characterized by the proliferation of more than 100 bargaining units across industry carriers under the administration of the Railroad Labor Act. Such a large number of units made it difficult for airline unions to cooperate among each other. Even though the industrial relations environment for airline workers lessened the negotiation strength of the industry unions, workers were able to attain relatively high wages because the major occupations such as pilots and mechanics are vital to carrier operations and command lucrative compensation.

Philosophical differences among union leaders led to the 1937 development of two major U.S. ocean shipping unions. The International Longshore and Warehouse Union (ILWU) under the leadership of Harry Bridges split from the International Longshoreman’s Association (ILA) and negotiated contracts primarily for workers on the West Coast. Both unions were able to negotiate high wages even though their members faced significant risk of job loss due to technological innovation. The ILA and ILWU’s monopolistic control over the supply of workers on the coasts contributed to their ability to secure high wages for their members.

INEFFICIENCIES ASSOCIATED WITH TRANSPORTATION REGULATION

Using regulation and state ownership as government approaches to promote universal and affordable transportation services unintentionally helped create a business environment that fostered inefficient operations and poor financial performance. Faced with rate regulation that removed price competition, transportation carriers often engaged in costly nonprice competition. For example, airline carriers provided passengers the convenience of nonstop service with frequent daily departure times as a strategy for distinguishing their service from that of rivals. This type of nonprice competition reduced carriers’ ability to fly with a significant number of seats filled per flight.

Rate regulation of ocean liners influenced carrier profitability by prohibiting them from directly negotiating low rates with inland transport carriers. Poor financial
performance was much more severe in rail and air transport as carriers in these industries were required to charge relatively high rates on high demand routes to subsidize servicing less profitable locations.

TRANSPORTATION SERVICES FOLLOWING DEREGULATION AND PRIVATIZATION
The potential for enhancing efficiency by promoting competition led to the deregulation and privatization of transportation sectors in the last quarter of the twentieth century. Deregulation gave carriers greater freedom to set rates and to enter markets previously restricted to incumbent carriers. This more competitive environment created a greater incentive for carriers to adopt cost-saving strategies across all transportation sectors. For instance, the introduction of the "hub-and-spoke" distribution system in the airlines industry resulted in a marked increase in the percentage of seats filled per flight. This type of system transports travelers from originating cities into a major airport, which is the airline’s hub. From the hub travelers from different originating cities are grouped together to take connecting flights to a common destination.

Postderegulation efficiency gains in the railroad industry were achieved in part by consolidating operations through mergers and by abandoning low-use routes. Efficiency gains in rail were further enhanced by carriers’ adoption of labor saving technologies such as electronic-based communications and information systems. New communications technologies in tandem with logistics software contributed to enhanced productivity in the trucking industry by allowing carriers to coordinate efficient delivery and pick-up schedules. Deregulation in the ocean liner sector facilitated efficiency gains by allowing these carriers to negotiate “door-to-door” rates. Such negotiations set rates for the international delivery of cargo to the final destination terminal inclusive of any inland transportation. These rates differ from the prederegulation requirement of “port-to port” negotiations that limit rate determination for transport freight from one port directly to another. Setting rates for the final destination allows liners to take advantage of economies of scale by choosing ports with the capacity to service large container ships and also provide intramodal service to the final destination point.

Privatization of public transit operations encourages cost savings by granting operating rights to low-bid service providers. Private providers are thought to have an advantage when competing for the provision of public services because managers in this sector are subject to more demanding incentives than those faced by their public sector counterparts. Evidence of public transit efficiency gains indicate cost savings in the range of 9 to 23 percent in the U.S., according to a 1988 report by Roger Teal. Similar cost savings from privatization are also reported for other countries.

SOCIAL IMPACT OF STEPPED-UP COMPETITION IN TRANSPORTATION
The labor market for transportation workers has been substantially influenced by the more competitive postderegulation and pro-privatization business environment. The pressure to lower costs led to declining work force sizes in U.S. rail and ocean shipping. The shift to greater efficiency and lower costs in ocean shipping also facilitated job loss in other countries. In 2006 James Peoples and colleagues reported that the introduction of new technology in the United Kingdom contributed to a 49 percent job reduction from 1989 to 1992. Ocean shipping jobs declined up to 66 percent at six major French ports following work rule reforms in 1992. Waterfront reforms introduced by the Australian government in 1989 contributed to a 42 percent reduction in stevedore jobs by 1991.

The approach toward labor cost savings did not result in a shrinking work force in U.S. trucking and airlines. Rather, the work force in these industry sectors grew over 70 percent in twenty years following deregulation, according to a 1998 report by Peoples. Declining labor costs in trucking and airlines were the result of eroding union wage premiums.

Transportation labor market changes influence other aspects of social welfare. For instance, the growing number of truck drivers on the road poses greater risk of environmental degradation from the emission of pollutants and greater risk of traffic accidents. Demand for quick service that places scheduling pressure on transportation operators further contributes to dangerous roads. Concerns over the social impact of increasing transportation demand promoted the enactment of several safety and environmental regulations following deregulation. In conjunction with safety-enhancing technologies, regulation limiting hours of operating service and regulations setting minimum standards for attaining driving permits helped the trucking industry avoid increasing injury rates following economic deregulation. Stiffer fuel efficiency standards and requirements for cleaner burning fuel have been enacted to help protect the environment from the debilitating health effects of emission pollutants.

In sum, the role of transportation services as an engine of economic growth will gain in importance during the twenty-first-century trend toward economic globalization. Those economies that are able to provide easy access to affordable services will enjoy a competitive advantage over other economies. In the future, such success will rely heavily on the ability to make efficient use of
non-renewable energy sources in addition to the ability to
develop new energy alternatives.

TRAUMA

Until the middle of the nineteenth century, the word *trauma* was used primarily to designate physiological injury emanating from an external event. Beginning in the 1860s, however, the term acquired additional significance when survivors and witnesses of industrial accidents began to show symptoms of trauma in the absence of any observable physical injury. These symptoms typically included mutism, amnesia, tics, paralysis, recurrent nightmares, and, in some extreme cases, psychic dissociation. Observing a pattern that linked exposure to an overwhelming event with forms of mental disorder, doctors coined the term *traumatic neurosis*.

One of the most remarked-upon features of this neurosis was the incapacity of the victim to recall the event that precipitated it, coupled with a simultaneous sensation...
of its recurrence in the present. For this reason, trauma quickly became understood not merely as a psychic injury but also as a wound in the memory. It therefore demanded particular techniques of memory recovery, which ranged over the century from hypnosis to narcotic therapies.

FREUD AND HIS FOLLOWERS
The crisis of memory was variously understood as a function of repression and/or nonsymbolic apprehension of an event. In Austrian Sigmund Freud's (1856–1939) later writings, trauma was conceived as the result of extreme psychic excitement, in which the mind's consciousness—which he analogized as a protective shield—was traversed by overwhelming stimuli, which were then registered in a different part of the mind, namely its unconsciousness. Precisely because the traumatic event had never become an object of consciousness, Freud theorized, it was unavailable for narration, objective reflection, and the analytic distance of the kind that would secure the subject against its frightening effects. For this reason, treatment focused on the method of abreaction, an induced revival of the event in which a subject, working with the therapist, would be able to render it conscious. The abreaction was also intended to produce a discharge, which then relieved the patient of a crippling, nervous energy.

Whether the efficacy of the treatment lay in the revival and cognitive apprehension and contextualization of the event or in the simple emotional relief obtained from the process was a matter of some controversy. Some argued that any event, even a false or confabulated one, could serve the purpose of treatment if its recall relieved patients of their symptoms. In the 1980s and 1990s, debates about the dubious validity of the "recovered memories" used in cases of alleged satanic or mass sexual abuse in the United States can be traced to this history of confabulation, coupled with the centrality of hypnosis in the treatment of trauma. Freud and his followers nonetheless insisted that the purpose of treatment was an intellectual reconciliation with the truth of experience, and hence the cathartic function of abreaction was played down in favor of a synthetic narrative or "talking cure."

Freud and his followers developed their theories and treatments largely in response to two kinds of phenomena, namely female hysteria (initially believed by Freud to be caused by sexual seduction of the girl) and "war neuroses." In both cases, charges of dissimulation (fakery) were often leveled against sufferers, and it was for this reason that Freud argued so fervently against the therapeutic deployment of fiction.

During wartime, the possibility of dissimulated illness acquired additional salience because soldiers who manifested acute forms of traumatic neurosis were relieved of their military duties. It was, in fact, the proliferation of cases of war neuroses (or "shell shock") that led to the burgeoning study of trauma in the early twentieth century. The centrality of war in the development of trauma theory has continued unabated since then.

POST–WORLD WAR II DEVELOPMENTS
Since World War II (1939–1945), two major developments have affected trauma theory: the experience of mass or collective trauma, especially that associated with the Nazi death camps, and the recognition of delayed developments of traumatic symptoms, or post-traumatic stress disorder (PTSD). In the first instance, individual experience has become paradigmatic of a general historical condition, and a person's incapacity to represent traumatic events has been translated into a suspicion of historical narratives that claim to represent the truth of collective violence. In the second, a historically verifiable event has been used to liberate individuals for recognition, treatment, and material compensation.

In some cases, events of mass suffering—such as the Holocaust, the atomic bombing of Hiroshima and Nagasaki, the Middle Passage of slavery, or the rape camps of Bosnia—are deemed uniquely unrepresentable. This is an argument of scale, but an ethico-political injunction emanates from it, prohibiting or restricting efforts to represent such horrors on the grounds that their actuality would be betrayed or diminished in the process. In some versions of this argument, the question of scale is either linked to or substituted with one of structure, according to which all representation is deemed inadequate or incommensurate with actual historical events (Caruth 1996). For proponents of this position, the purpose of historical narration is the communication of traumatic effects to others—secondary witnesses and historical heirs—a process that is said to facilitate identification between those who have survived and those who have not. This argument has been widely criticized, however, because it fails to differentiate between those who suffered or witnessed events firsthand and those whose encounters with trauma were mediated by narratives of others who suffered them in actuality.

The question of PTSD has attracted similarly widespread debate. Observing that the syndrome was recognized only through advocacy on behalf of U.S. military veterans (PTSD was added to the Diagnostic and Statistical Manual of Mental Disorders of the American Psychiatric Association in 1980), some have suggested that presentation of symptoms and prevalence rates are influenced by the possibility of compensation for injuries. Moreover, as the authority of PTSD and American psychiatry has assumed international dimensions, new questions have arisen about the cross-cultural validity of the
concept of trauma. In Vietnam, for example, there is considerable resistance to the idea of veterans suffering from PTSD. In Japan the diagnosis was rarely made prior to the Kobe earthquake of 1995, despite the country’s long experience of acute postwar ailments.

Two factors explain the differential diagnosis of PTSD on a global scale, one cultural, the other politico-economic. First, there are many culturally distinct vocabularies and methodologies for identifying and treating shock and its psychosomatic aftermath. In some Buddhist societies of Southeast Asia, a sudden fright or accident is said to cause a dissociation of the person’s spiritual being and requires rituals that call back or rebind dislodged spiritual essences. In parts of Africa and in aboriginal America, shock may be adduced as a causal factor in some illnesses and is often said to precipitate birth crises. It may be treated with combinations of naturopathic and ritual methods.

Second, the widespread recognition of shock as a source of injury and the prevalence of ideas of dissociation that accompany vernacular knowledge about shock resonate strongly with Western medical concepts of trauma, though Western medicine increasingly attributes the disturbing symptoms of PTSD to chemical transformations of the brain, especially in the hippocampus, amygdala, and cerebral cortex. The diagnosis of PTSD, however conceived, has nonetheless been promoted by international humanitarian organizations as a mechanism for obtaining financial resources and mental health services for populations—displaced by war and natural disaster—that would otherwise lack them. Invoking PTSD as a basis for claiming human rights is not without risks, however. The inherent focus on traumatic events in its diagnosis (which requires that the symptoms of hyperarousal and/or withdrawal be linked to an originating event) often displaces concern for the structural sources of long-term social and psychic suffering, including that caused by homelessness, poverty, unemployment, or long-term political oppression. Moreover, the proliferating tendency to invoke trauma as a synonym for unpleasant experiences in popular media and public discourse threatens to dissipate the term’s medical as well as its ethical-political force. Beyond the risks that it is subject to both trivialization and economic utilitarianism, however, most theorists agree that trauma is a phenomenon whose increasing occurrence is inextricably tied to the industrialization of war and the massifications of modernity.

TRAUMATIC BONDING

In contrast to normative bonds and attachments, which are characteristically affectionate and protective, traumatic bonding refers to a counterintuitive variation in which one member of the bonded pair intermittently victimizes or traumatizes the other person. The term traumatic bonding was first employed to describe a powerful and destructive bond that is sometimes observed between battered women and their abusers, or between maltreated children and their caregivers (Dutton and Painter 1981). It has since been applied more generally to describe strong emotional ties that may form between victims and their oppressors across a range of relationships and types of abuse (e.g., the Stockholm Syndrome; see Strentz 1980).

The necessary conditions for traumatic bonding are that one person must dominate the other and that the level of abuse chronically spikes and then subsides. The relationship is characterized by periods of permissive, compassionate, and even affectionate behavior from the dominant person, punctuated by intermittent episodes of intense abuse. To maintain the upper hand, the victimizer
manipulates the behavior of the victim and limits the victim’s options so as to perpetuate the power imbalance. Any threat to the balance of dominance and submission may be met with an escalating cycle of punishment ranging from seething intimidation to intensely violent outbursts. The victimizer also isolates the victim from other sources of support, which reduces the likelihood of detection and intervention, impairs the victim’s ability to receive countervailing self-referent feedback, and strengthens the sense of unilateral dependency.

The traumatic effects of these abusive relationships may include the impairment of the victim’s capacity for accurate self-appraisal, leading to a sense of personal inadequacy and a subordinate sense of dependence upon the dominating person. Victims also may encounter a variety of unpleasant social and legal consequences of their emotional and behavioral affiliation with someone who perpetrated aggressive acts, even if they themselves were the recipients of the aggression.

Theoretical explanations for this phenomenon are divergent and controversial. Psychodynamic theorists have employed concepts such as masochism, repetition compulsion, and identification with the aggressor (van der Kolk 1989; Young and Gerson 1991) to explain how such seemingly self-destructive relationships can be formed. A central developmental tenet of this perspective is that a proclivity toward abusive relationships and traumatic bonds is rooted in the victim’s traumatic childhood attachments. Attachment theory has also been applied to explain traumatic bonding as an unresolved form of insecure attachment (Saunders and Edelson 1999) in which the capacity for self-regulation has been impaired by the alternately abusive and protective actions of an attachment figure. Each of these perspectives has persuasive elements, but the explanatory mechanisms are difficult to operationalize and have therefore gone untested.

Learning theory offers an explanation based on the consistent finding that intermittent reinforcement schedules can strengthen and maintain behavior even during periods when the reinforcer is absent. In the cycle of relational behavior attributed to traumatic bonding, the victimizer applies intense punishment, then negatively reinforces compliant behavior from the victim by ceasing the punishment, and soon after shifts to lavishing the victim with various forms of noncontingent positive reinforcement. This pattern of punishment and reinforcement may constitute a particularly powerful form of double-bind or vicious cycle, especially given the victim’s legitimate fear of being injured or killed in retaliation for any act of defiance.

Little empirical research has been published examining the individual and situational characteristics that predict the development and maintenance of traumatic bonding. Some support has been found both for the construct of traumatic bonding and for the importance of the intermittency element for predicting postrelationship distress among victims (Dutton and Painter 1993). But the most perplexing and counterintuitive aspect of traumatic bonding—the victim’s feelings of affection and longing toward the victimizer following termination of the abusive relationship—has not been studied with the kind of rigor that would provide definitive findings, and the sociopolitical and philosophical aspects of this phenomenon make it particularly difficult to address from a scientific perspective.

TRAVEL AND TRAVEL WRITING

Modern notions of travel have their roots in a diverse history of developments; groups of people have moved across landscapes for the purposes of migration, pilgrimage,
trade, exploration, and colonization. For example, humans have migrated for resettlement for a million years, and for agricultural reasons for tens of thousands of years. Similarly, pilgrimages have been the cornerstone of most major religions: Just as the ancient Greeks sought the oracle at Delphi, Buddhists travel to the city of Buddha’s birth, Muslims make the hajj to Mecca, and Christians visit Jerusalem. In another parallel flow of travel, trade routes flourished between Europe and China from the rise of Greek civilization to the fall of the Roman Empire.

MODES OF TRAVEL THROUGH HISTORY
The Mediterranean, which served as a vast network of people and places enriching communities for centuries, spurred commerce and exploration as twin historical processes—climaxing in the Age of Exploration between the fifteenth and seventeenth centuries. New technologies of cartography, navigation, warfare, and shipbuilding allowed travelers and traders to extend their reach beyond the Mediterranean—notably, Christopher Columbus’s (1451–1506) arrival in the New World in 1492 and Vasco da Gama’s (c. 1469–1524) trip around the Cape of Good Hope in 1498. Just as religion compelled pilgrimages, it has also inspired exploration and colonialism, either through evangelism or through groups fleeing religious persecution.

One of the first organized forms of travel that was neither explicitly religious nor commercial was the “grand tour.” Beginning in the mid-1600s, it became fashionable for young British elites to take an expedition, as both a rite of passage and a duty. The grand tour was an extended journey through Europe, wherein a young man would travel in order to become more cultured and educated. Because of its courtly manners, high fashion, rich history, and sophisticated language, Paris was a common stop, but Italy, Switzerland, and Germany were also preferred destinations.

Industrialization, however, brought this trend to an end and ushered in a new era. Travel in the modern age can be traced to Thomas Cook (1808–1892), who would transport up to five hundred people at a time on train trips across England beginning in 1841. While tours from the ancient age through the grand tour tended to be a privilege of the rich, Cook’s standardized tours aimed at mass appeal. Shadowing the ancient tradition, but also forecasting the powerhouse industry to come, Cook packaged trips to Egypt that followed the exact route the Romans traveled in 19 CE. Mass production of travelogues and improved transportation sparked the collective imagination and made travel more accessible to the masses.

The rise of cities brought about a newfound curiosity in urban life that also echoed more ancient times. Just like the Romans, nineteenth-century New Yorkers regularly toured their own city for entertainment, desiring brief, controlled exposure to “the other half,” with its commoner struggles, immigrant communities, and what was seen as deviant sexual practices (which inspired slumming parties, wherein people would pay to rub elbows with Lower East Side homosexuals). Similarly, international visitors like Charles Dickens (1812–1870), Alexis de Tocqueville (1805–1859), and Frances Milton Trollope (1779–1863) were coming as early as the end of the American Revolution (1775–1783) to write travelogues of the national social experiment—with its racial and cultural mix, class inequalities, and vast geography.

Originally the purview of the elite, diplomats, and rugged explorers, travel since the 1960s has become widely available to working and middle-class people. By 2000, tourism and travel had become the world’s largest industry, which, according to the World Travel and Tourism Council, produces up to 10 percent of the world’s economic output and employment.

TRAVEL WRITING
Along with travel comes the parallel cultural production of travel writing. While Petrarch’s (1304–1374) description of his ascent of Mount Ventoux in 1336 is often traced as a progenitor of travel writing, the practice blossomed with the consolidation of British hegemony in the 1800s, when expansion and empire matched eager public fascination as stories of Native Americans and the Opium Wars with China were produced for the masses. The impact of travel writing as a newfound form of nonfiction valorizing British economic and political values can be found in the works of writers such as Dickens, William Thackeray (1811–1863), Joseph Conrad (1857–1924), and Rudyard Kipling (1865–1936).

Perhaps no writing of that era was more dramatic, popular, and controversial as that of explorer, writer, poet, and diplomat Sir Richard F. Burton (1821–1890). Stirring public fascination with his adventures, Burton (who made the first English translations of Arabian Nights and the Kama Sutra) traveled disguised as an Afghan physician throughout the Middle East. “Passing” well enough to have entered Mecca, the heart of the Muslim world, in 1853, he gave the Western readers their first glimpse into that unknown land. Travel writing has always been particularly keyed toward the cultural translation of “unknowns,” and Burton often displayed his dual roles of explorer and poet as he communicated the connections and differences between disparate cultures to his Victorian readers: “the pigeons of Mecca resemble those of Venice” (Burton [1855] 1964, p. 174).

The notion of cultural translation infuses problems of representation, and cultural theorists, ethnographers,
postcolonial thinkers have questioned the colonizing and misguided gaze of the Western observer (Clifford and Marcus 1986). The dialectic of cross-cultural exchange has been criticized as being imbued with power relations that predominately favor the more dominant cultures. Burton, for example, had to serve the imperialist economic and political needs of the Royal Geographical Society and the British East India Company, as well as his own desires for exploration and translation. Missionaries of the British Empire were similarly wrought with tensions as they wrote of their travels: On the one hand, they attempted to fulfill their religious and moral duties as benevolent evangelicals, and on the other hand they had to maintain the interests of the crown.

Such pressures are found throughout travel writing, as authors aspire for objectivity yet struggle with their own subjective experiences and moral concerns—whether they toured Bali or New York’s Bowery. This perspective is perhaps best evidenced in the scholarly realm by Claude Lévi-Strauss’s ambiguous narratives of *Tristes Tropiques* (1955), a text often used by those wishing to criticize the colonizing power of ethnography and travel. Just as the grand tour served as a form of education and entertainment, those dual functions also play important roles for both the traveler and travel writing, in and out of the scholarly realm.

The contemporary moment is marred for many in the field, as they dread increasing “homogenization,” “commodification,” and “banalization” of culture—what some have called Disneyfication. While making travel and travel writing more accessible, industrialization and mass production have also caused some cultures to be carefully packaged in order to attract visitors, as tourism and culture scholars like Dean MacCannell (1976) have noted. Mass travel and travel writing, it is feared, summarizes culture and cities into “sets” of a few places and experiences that prejudice the visitor into particular expectations before arrival. This, however, is an ahistorical perspective, as even ancient Romans would feel contented to have seen the world so long as they had gazed upon each of the Seven Wonders—the original “best-of” list devised by an unknown scholar in the third century BCE. There was also Homer’s *Iliad*, another form of writing that established a path around which a travel infrastructure could sprout: hotels and restaurants to fill basic needs, and droves of guides ready for hire to present the alleged armor of Trojan War heroes, the beach where Greek ships landed, or where Achilles and Ajax were buried. These antiquarians kept close to the beaten path, seeking out the perceived cornerstones of their own cultures (Casson 1974).

It is, perhaps, because of this juggernaut tourism and travel industry that travel writing has returned to the journeys of earlier epochs. Several popular press books trace the paths of Captain James Cook (1728–1779), antiquarian tourists, the Indian god Rama, and a Buddhist monk’s seventh-century journey down the Silk Road. These travel writings match up contemporary journeys with those of their ancient forebears. Such a trend is evident in the social sciences as well: Indian anthropologist Amitav Ghosh (1993), for example, blends a contemporary narrative as he attends school in Alexandria, Egypt, with the story of a twelfth-century Jewish merchant and his Indian slave.

**TREASURY VIEW, THE**

In April 1929 the British chancellor of the exchequer, Winston Churchill (1874–1965), defended “the orthodox Treasury doctrine which has steadfastly held that, whatever might be the political and social advantages, very little additional employment, and no permanent additional employment can, in fact, and as a general rule, be created by state borrowing and state expenditure” (House of Commons 1929, p. 54). Churchill’s comment, made during the 1929 general election campaign, was designed to blunt opposition proposals for large-scale public works to reduce unemployment. Churchill’s view was reinforced the next month by a white paper restating the practical and doctrinal objections to public works. The issues were aired again in an examination by the economist John Maynard Keynes (1883–1946) of the senior Treasury official Sir Richard Hopkins (1880–1955) before the Committee on Finance and Industry (established by Labour prime minister Ramsay MacDonald [1866–1937]...
in 1929 to examine the impact of the financial system on the economy).

Britain did not launch an expansionist policy against unemployment (comparable to that implemented in Sweden after 1936), and some have identified the “Treasury view” as the main obstacle. Histories of economic thought published during the “Keynesian era” (such as Michael Stewart’s *Keynes and After* [1969]) blamed the grip of outmoded ideas on senior Treasury officials. The opening of Britain’s public records brought a new agenda to the debate. A number of historians found in interwar Treasury papers little doctrinal argument but many practical administrative difficulties, most of which related to the Treasury’s management of public finance. However, the (delayed) release of further Treasury papers to the Public Record Office in mid-1986 allowed Peter Clarke (1990) to create a more complex analysis. He demonstrated that in the early 1920s senior Treasury officials believed that British prosperity depended upon firm commitment to the liberal international order: the gold standard, free trade, and the balanced budget. This was the “knave-proof” fiscal constitution that senior British officials had deployed against the grandiose, expansionist ideas of cabinet ministers from 1918 to 1919. It held that the ultimate causes of unemployment lay in lagging exports and could be remedied by industrial modernization, lower unit labor costs, and higher foreign lending (within limits). Thus, diverting money into home investment would exacerbate the problem.

Personnel changes, growing recognition that the gold standard adjustments had not worked, and the impact of the return from Harvard University of the economist R. G. Hawtrey (1879–1975, a senior Treasury official but with limited day-to-day influence over policy) brought a new, more flexible approach from 1930. Hawtrey demonstrated the stickiness of the gold standard adjustment processes, underlined the possible effectiveness of reflationary finance, and encouraged Hopkins and others to think more creatively and flexibly about economic relationships. This paved the way for a still more productive interchange between Treasury officials and leading economists in the 1930s, as noted by Susan Howson and Donald Winch (1977).

Unfortunately, econometric work has suggested that “Keynesian” policies offered only a palliative to Britain’s interwar unemployment problem. T. Thomas’s macro-model (1981) of the interwar economy and Sean Glyn and Peter Howells’s calculation (1980) of the interwar multiplier both pointed to the extreme improbability that unemployment could be reduced to “normal” levels by monetary and fiscal policy. Thus, one is left with the conclusion that the Treasury view may have acted as a barrier to independent, expansionist policies at a critical moment, but it was only one of a number of impediments, and the bold assumptions of Keynes and the Keynesians, both at the time and during the 1950s and 1960s, that there was an easy solution to unemployment were misplaced.

**TREATY FEDERALISM**

Treaty federalism, also referred to as treaty constitutionalism, is a concept that explicitly identifies negotiated agreements between aboriginal people and other sovereign actors as constitutional documents. In this interpretation, treaties are considered founding political documents between two sovereign parties that at once establish a delegation of power or areas of shared responsibility as well as a retention of autonomy for each signatory. Treaties therefore establish a constitutional order that gives force to the central concept of federalism: a constitutionally guaranteed system of both shared and self-rule.

Using treaties or negotiated agreements as the primary mechanism for establishing and defining a political
relationship between sovereign parties has important historical precedents in both nonaboriginal and aboriginal contexts. In British North America, intra-aboriginal political relationships were thus established among the Mi'kmaq, the Iroquois, and the Blackfoot. The use of treaties to establish political relationships and to define land rights between the British Crown and aboriginal people found strong expression in King George III’s Royal Proclamation, 1763. A period of historical treaty making continued in what are now former British colonies, with these periods concluding in the United States in 1871, Canada in 1923, and New Zealand in 1840. This historical practice was not universal, however, as British colonial powers did not recognize aboriginal rights in Australia and no treaty-making practice was there established. A contemporary round of negotiated agreement making was reestablished in Canada in 1973 and in New Zealand in 1989. Australia’s Native Title Act, first enacted in 1993, establishes a statutory framework for negotiated agreement making, and there is ongoing political discussion regarding the meaning and effect of a treaty between Australian governments and aboriginal peoples.

The concept of treaty federalism pushes the standard interpretation of the founding constitutional order of many countries. It argues that treaties between aboriginal people and the states of the New World are the source of these states’ constitutional legitimacy and territorial sovereignty. Following from this view, states are considered fundamentally illegitimate if treaties are not respected or inadequately implemented. It also follows that states that have not negotiated with the descendent communities of its prior occupants exercise state sovereignty on illegitimate grounds.

The arguments raised by the treaty constitutionalist position point to a very different conception of the appropriate constitutional and legislative relationship with aboriginal people. As historical treaties were largely limited documents and did not include provisions over many aspects of aboriginal life, territory, and governance, it is argued that those areas outside the treaties remain within the exclusive jurisdiction of aboriginal people. As they did not cede or delegate responsibility over many issues to colonial powers, a treaty constitutionalist position holds that the jurisdiction to address these areas remains with aboriginal people according to aboriginal laws. It also necessarily holds that state action in areas not mentioned within the treaties would be ultra vires, or outside its jurisdiction.

In states that are constitutionally federal—ones that are divided into two levels of government, each guaranteed a degree of autonomy—the treaty constitutionalist position argues that the assignment of constitutional responsibility for aboriginal affairs to either the federal or subnational level of government cannot be interpreted as an assignment of constitutional power or sovereignty over aboriginal people. For instance, it would deny that section 91(24) of Canada’s Constitution Act, 1867, granted the Canadian federal government the power to legislate for “Indians, and Lands reserved for Indians” without their consent. Treaty constitutionalists argue instead that the scope of section 91(24) is constitutionally limited to those issues explicitly delegated under the treaties and that in no way would those issues include a complete delegation of aboriginal sovereignty. In this reading, section 91(24) merely identifies the federal government, not the provinces, as having the responsibility of implementing existing treaty obligations and negotiating future agreements with aboriginal people, as befitting a nation-to-nation political relationship.

A treaty constitutionalist position necessarily implies that the judicial review of existing and future treaties between aboriginal people and other governments should be governed by conventions of constitutional interpretation, a higher standard of interpretation than that regarding normal contract law.

TRENDS

A trend is a relatively smooth and unidirectional pattern in data that arises from the accumulation of information over time. Many of the time series in economics and in other social sciences exhibit a smooth (upward or downward) tendency. In developed economies, the macro-socioeconomic time series, such as gross national product, consumption, income, and population, are characterized by an upward trend. Though in the short run the economy goes through expansions and recessions, in the long run there is growth. This is due to technological progress and/or population growth. The trend arises from the accumulation of socioeconomic activity from one period to the next. For instance, the time series of the U.S. population has an upward trend over time because the number of births exceeds the number of deaths and/or because the number of immigrants exceeds the number of emigrants.

From an econometric point of view there is a distinction between deterministic and stochastic trends, depending on whether the accumulation of information is due to a deterministic or to a random component. Suppose that an economic variable \( Y_t \), for instance national product, can be represented by a model such as \( Y_t = a + bt + \varepsilon_t \) for \( t = 1,2,3,... \). In this case, the trend is a line \( a + bt \) with \( a \) as intercept and \( b \) as slope, which is also the growth rate. Because \( t = 1,2,3,... \) is purely deterministic, the trend is deterministic. An example of an exponential deterministic trend is the time series of the U.S. population. Conversely, a stochastic trend is generated by the accumulation of random components. An example of a model with a stochastic trend is \( Y_t = \varepsilon_t + \varepsilon_{t-1} + \varepsilon_{t-2} + \ldots + \varepsilon_1 \) where \( \{\varepsilon_t\} \) is a collection of normal random variables. An example of a stochastic trend is the time series of speculative prices such as stock prices or exchange rates. The time series generated by deterministic trend models tend to be smoother than those generated by a stochastic trend.

Deterministic trends may have different shapes. Among these, the most common are linear, quadratic, exponential/logarithmic, and logistic. Only when the trend is linear is the growth rate constant. In any other specification, the growth rate will depend on the time period under study. Models with a deterministic trend are also known as trend-stationary models because all the unconditional moments, with the exception of the mean, are time-invariant. Their estimation and testing is straightforward because standard statistical results apply. In the linear trend model specified above, the parameters \( a \) and \( b \) can be estimated by Ordinary Least Squares (OLS), assuming that the error term is well-behaved. Hypothesis testing relies on tests that have standard asymptotic distributions, such as the t-ratio and F-tests.

Stochastic trends are more complicated than deterministic trends because they are non-stationary. Their statistical analysis requires the use of non-standard asymptotic distributions, which need to be obtained by simulation techniques. The model introduced above, \( Y_t = \varepsilon_t + \varepsilon_{t-1} + \varepsilon_{t-2} + \ldots + \varepsilon_1 \), has the following equivalent representation \( Y_t = Y_{t-1} + \varepsilon_t \), which is an autoregressive process of order one with an autoregressive parameter equal to one. This model is also known as a unit root process or random walk without drift. If the model includes a constant such as \( Y_t = \varepsilon_t + Y_{t-1} + \varepsilon_t \), one says that the process is a random walk with drift. The drift produces a smoother upward (or downward) tendency. Unit root processes are non-stationary because the unconditional moments (mean, variance, and covariances) are increasing functions of time. The autocorrelation function of a unit root is very characteristic with autocorrelation coefficients of any order asymptotically equal to one.

From an empirical perspective it is important to differentiate a deterministic trend model from a stochastic trend model. There are two main reasons for this: the need to conduct the correct statistical inference, and the construction and interpretation of the correct forecast. Consequently, the first step in empirical research is testing for unit root, which is a test of non-stationarity versus stationarity. In a model such as \( Y_t = \varepsilon_t + \varphi Y_{t-1} + \varepsilon_t \), the null hypothesis is set as \( H_0: \varphi = 1 \) (non-stationarity) versus an alternative \( H_1: \varphi < 1 \) (stationarity). Under the null, the standard t-ratio is not normally distributed but has a non-standard distribution, which is known as the Dickey-Fuller (DF) distribution. The DF critical values are tabulated by numerical simulation. A rejection of the null in favor of the alternative hypothesis means that the process does not have a stochastic trend. On the contrary, failure to reject the null hypothesis means that there is not enough evidence against the unit root process and a stochastic trend in the data should be entertained.

From a forecasting perspective, a deterministic trend model produces a forecast along the time trend specification. The uncertainty associated with the forecast is bounded regardless of how far into the future one wishes to predict. However, a forecast from a stochastic trend model has unbounded uncertainty as the variance of the forecast is an increasing function of time.

A pervasive problem in empirical research in the social sciences during the 1970s and 1980s is the case of spurious regression. Regression is spurious when two (or more) variables, \( Y_t \) and \( X_t \), are found to be correlated but in fact they are not. This finding arises because \( Y_t \) and \( X_t \) are non-stationary (unit root processes) and a regression of \( Y_t \) on \( X_t \) does not take into account the stochastic trend. The diagnosis of spurious regression is relatively simple. If the R-squared of the regression is extremely high, around 0.90 and above, the t-statistics are exceptionally large, and the Durbin-Watson statistic is low, it is highly likely that
the regression of \( Y_t \) on \( X_t \) is spurious and, consequently, there is no correlation between them. The correct approach to analyze the correlation between \( Y_t \) and \( X_t \) is first to remove the stochastic trend and then to run the regression. By first-differencing the data, the stochastic trend is removed. For instance, if \( Y_t \) and \( X_t \) have a unit root, for example \( Y_t = Y_{t-1} + \varepsilon_t \) and \( X_t = X_{t-1} + \nu_t \), the first difference of \( Y_t \) is \( \Delta Y_t = \varepsilon_t \) and the first difference of \( X_t \) is \( \Delta X_t = \nu_t \). The proper regression is to regress \( \Delta Y_t \) on \( \Delta X_t \). However, if \( Y_t \) and \( X_t \) have a deterministic trend, the data should not be first-differenced but the regression of \( Y_t \) on \( X_t \) should contain a deterministic trend specification. There is only one instance in which a regression of \( Y_t \) on \( X_t \), being both unit root processes, is meaningful. This is the case of cointegration, in which \( Y_t \) and \( X_t \) share the same stochastic trend. In this instance there is a long-run equilibrium between both processes.

TRIARCHIC THEORY OF INTELLIGENCE
SEE Multiple Intelligences Theory; Intelligence.

TRIBALISM
The concept of *tribalism*, like that of the *tribe*, is difficult to define precisely, as it is closely interwoven with the context in which it is used. Tribalism may be defined as the maintenance by a tribal society of its organization, ways, and autonomy in the face of change. But tribalism may be defined differently when a tribe’s claim of identity has less to do with its primitivism or indigeneity than with its ethnic discretness and cultural distinctiveness for gaining material or political advantages. In fact, tribalism does not exist in any objective sense—hence the problem in defining the concept.

Early ethnographic writings offer examples of “we-feeling” among the members of a particular tribe that set it apart from neighboring tribes. Ethnographers called this tribalism and linked it to the notion of ethnocentrism, but particularly associated with tribal people. For example, when the Zulu people of South Africa name themselves as *isizwe*, meaning a nation or a people different from other tribes, or the Birhor of India distinguish themselves as *bor* or people from *diku*, an explicit reference to tribalism is made. Therefore, tribalism is the manifestation of a collective group identity based on common natural impulses such as fear, desire, necessity, or ethnic distinctiveness.

Vine Deloria Jr. proposes in his 2003 book that, from the Native American perspective, tribalism has four dimensions: spatial, social, spiritual, and experiential. The spatial dimension connects the tribes with their land, which is for them a precious possession. The social dimension refers to the social cohesion that binds the members of the tribe together. The spiritual dimension refers to the idea of the people as a religious conception. The experiential dimension is the sharing of history, culture, rituals, and traditions. For Deloria tribalism has to be practiced; it is more than a philosophy, it is a way of life.

Since the late twentieth century, tribalism in the Middle East, Africa, and South and Southeast Asia has generated some dangerous and divisive tendencies. Tribalism is positive when the complete allegiance of a collectivity is geared toward the collective good—nation building, preserving the group identity as a single cohesive unit that fosters ethnic solidarity, seeking new dimensions of development. Contrarily, tribalism is negative when it generates ethnic hatred and war. The intertribal warfare and ethnic divide in Africa is tribalism’s worst manifestation. Another example of negative tribalism is the disintegration of Yugoslavia in the early 1990s into smaller competing states. Whereas positive tribalism needs to be fostered for the sake of collective tribal identity, negative tribalism that threatens to give rise to terrorism and political turbulence must be thwarted. The genocide of nearly one half million Tutsis by the Hutu extremists in 1994 in Rwanda and the ethnic cleansing in the former Yugoslavia in the 1990s are painful commentaries on negative tribalism.

Given both its positive and negative manifestations, tribalism is closely related to ethnic solidarity and ethnocentrism. But it is one step ahead of racism, as the conflicts of the early twenty-first century in Somalia, India, Pakistan, Afghanistan, Sri Lanka, Turkey, and Indonesia are between ethnic groups or tribes rather than between the races.

In his 2006 article, Howard Campbell discusses two major approaches to tribalism that suggest revisions to anthropological notions of tribes and indigeneity from a Native American perspective. According to one approach,
“ethnic identity is never essential and … identity change is quite common” in tribal cultures; the second approach asserts that native tribes persist “by production of symbolic representations” rather than through the “performance of aboriginal traditions in everyday life” (Campbell 2006, p. 296). In view of the rising trend of neotribalism in India, with similarities to the Native American experience, “protective discrimination” has consolidated hitherto dispersed tribal groups into organized pressure groups to fight for their legitimate constitutional rights. In 2005 the Indian state of Sikkim recognized the Lepcha community as the “Most Primitive Tribe”—a distinction that signals the tribe’s relatively high standard of living and confers status and privileges. Sometimes it becomes necessary for a tribe to reinvent itself, as in the case of the Ngati Kuri of New Zealand, whose name did not appear in the list of the country’s recognized tribes. Tribalism, therefore, is a fluid concept with both positive and negative connotations that must be understood with reference to specific contexts.

### TRIBE

Despite its popular as well as academic usage, *tribe* is a contentious concept. In popular imagination, *tribe* is associated with “primitivism” and “backwardness,” clearly referring to non-Western or indigenous groups inhabiting the countries of Asia, Africa, and Latin America or to American Indian reservations. In 1951 the Royal Anthropological Institute defined the tribe as a “politically or socially coherent and autonomous group occupying or claiming a particular territory” (1951, p. 66). Scholars since then have contested the notions of coherence, autonomy, and territorial segregation as only ideal constructs, devoid of much empirical support. Although it is unlikely that this definition would apply perfectly to any single tribe, theoretically *tribe* is construed as a group or community sharing a common territory, speaking a common language or dialect, sharing a culture and religious tradition, united under a single political organization, and having a common economic pursuit. Therefore, as André Béteille (1981) observes, the existence of a tribe fitting any theoretical definition is at best an anthropological imagination.

Morton Fried suggests that what anthropologists study today is “tribe as a secondary sociopolitical phenomenon, brought about by the intercession of more complex ordered societies, states in particular.… The ‘pristine tribe,’ on the other hand, is a creation of myth and legend, pertaining either to the golden age of the noble savage or romantic barbarism” (1975, p. 114). As Archie Mafeje notes, in Africa “the indigenous population has no word for ‘tribe’… Traditionally, people were identified by territory—‘Whose [which Chief’s] land do you come from’ ” (1971, p. 254). This is true also for India, where there is no lexical equivalence of the English word “tribe”; it began to be used by the British administrator-anthropologists only for administrative convenience.

In the United States and India, tribes today refer to the indigenous or autochthonous people, legally recognized groups that enjoy some degree of autonomy and state protection. In India, for example, the Constitution makes special provisions for the protection and welfare of its “Scheduled Tribes,” a legal-administrative category within the nation.

**HISTORY AND DEVELOPMENT OF THE CONCEPT**

When European colonial expansion was at its peak during the sixteenth and seventeenth centuries, the writings of missionaries, traders, and adventurers resulted in the genre of ethnography of the peoples they encountered, whom they called tribes. The tribes were deceptively painted to be in the primal stage of human cultural evolution, the culmination of which was, in the minds of the Europeans, advanced European civilization. The legacy of this Eurocentric notion was inherited by the anthropologists of the eighteenth and nineteenth centuries. In the latter half of the nineteenth century, within the domain of anthropology, unilineal or classical evolutionists like Lewis H. Morgan (1818–1881) hypothesized tribe as a transient stage in the process of cultural evolution from early hunters and foragers to agrarian societies. With the collapse of classical evolutionism at the beginning of the
tenth century and the consolidation of the field of anthropology in Great Britain, scholars like E. E. Evans-Pritchard used a structural definition of tribe, particularly in the context of segmentary societies like the Nuer of Sudan, which he discussed in his 1940 book. Later, Marshall Sahlins, in his 1968 study, characterized tribes with segmentary lineages that were different from centralized chiefdoms.

Taking cue from Wilson and Wilson, Lewis introduced the concept of “scale” in characterizing a tribe. He contended, “Ideally, tribal societies are small in scale, are restricted in the spatial and temporal range of their social, legal, and political relations, and possess a morality, religion, and world view of corresponding dimensions” (1968, p. 147). In the 1970s the Marxist anthropologist Maurice Godelier, while attempting a critique of the concept, cautioned that “tribe” was used as a tool by the powers who dominated the Third World and warned that “we cannot silently bury it with a mere death sentence, or stigmatize those who continue to use it with the epithet ‘infamous’ empiricism.” Godelier argued that new concepts would not resolve the problem; thus the “concept of the ‘tribe’ will continue to be used in more or less refined forms and will deliver the same goods and the same kind of bad service” (1977, pp. 95–96). Despite Godelier’s exhortation, in subsequent decades post-structuralist, postmodern, and feminist theorists such as Lila Abu-Lughod and Michael Gilsenan deconstructed the colonial legacy of the concept and pleaded for a more reflexive and dialogic ethnography. All these controversies notwithstanding, there is nothing wrong in using the term tribe, so long as it conveys the real sociopolitical formation and cultural distinctiveness of a group rather than myths, stereotypes, and prejudices. However, anthropologists have come to prefer the term ethnic groups over tribes.

For many, as Susana Devalle (1992) notes, tribe is understood as a “colonial category” to promote specific colonial interests and is largely associated with the Western colonial power structures and discourses. Yet Fried (1975) persuasively argues that in the past in many expansionist states, such as China, the relatively weaker peoples conquered by the stronger groups were given pejorative terms on a par with “tribe.”

BASIC CHARACTERISTICS
In the absence of a clear-cut definition, it is useful to examine the ways in which tribes are characterized. A tribe is ideally designated as having a common territory, a common name and culture, speaking a common language, practicing endogamy, with an autonomous political organization and close-knit kinship ties, the members of which are believers of a common religion. The classical anthropological depiction of tribes, as put forward by Mafeje, as “self-contained, autonomous communities practicing subsistence economy with no or limited external trade” (1971, p. 257) is highly polemical, as ethnographies hardly support this utopian construction. Far from being autonomous or self-contained, tribal communities have more often fostered multiterial units that functioned as bigger kingdoms or confederacies. The Luapula Kingdom of Kazembe in Central Africa, the Zulu empire in South Africa, the Ashanti Confederacy in West Africa, and the Gond kingdoms of India are good examples of, in Mafeje’s term, “super-tribes.” Realistically, tribal communities as “little traditions” in the civilizational model of Robert Redfield (1956) have interacted politically, economically, and ritualistically with larger sociopolitical formations in their neighborhoods. The process of Sanskritization suggested by M. N. Srinivas (1966), Nirmal K. Bose’s model of Hindu methods of tribal absorption (1967), and Surajit Sinha’s case studies on state formation in tribal India (1987) are classical examples of the fact that neither in the past nor at present have tribes remained secluded or insulated either politically or culturally, despite having their own chiefs or heads, territorial affiliations, and customary laws.

Tribes also economically interact with other neighboring tribes and nontribes, and yet have their own means of subsistence. Many of them still practice hunting and foraging (the !Kung of Botswana and Namibia), pastoralism (the Masai of Kenya and the Nuer of Sudan), swidden agriculture (the Pgakenyaw and Lua of Thailand, Uma’ Jalan of East Kalimantan), settled cultivation (the Kikuyu of Kenya and the Mundu and Santal of India), or traditional crafts (the Uraali Kurumas of South India), or more realistically, a combination of them. Although tribal societies may not be stratified, primordial forms of social differentiation do exist in them, as noted by Kamal Misra (1991); and despite practicing many different faiths, animism still forms the bedrock of their religion.

SCHEDULED TRIBES IN INDIA
Approximately 8.2 percent of the total Indian population has been designated as “Scheduled Tribes” (STs), according to the Indian census of 2001. The official Web site of the Ministry of Tribal Affairs, Government of India, states that “the Scheduled Tribes are the tribes or tribal communities or part of or groups within these tribes and tribal communities which have been declared as such by the President through a public notification.” The Indian government regards retention of “primitive” traits, geographical isolation, possessing distinct culture, shyness of contact with the community at large, and economic backwardness as the essential characteristics of Scheduled Tribes. However, most of these communities are in close proximity and constant interaction with the neighboring Hindu peasants. Some of the tribal groups are now almost
extinct—the Great Andamanese number only twenty persons—whereas others, like the Gonds, number more than five million. They are still at different stages of economy, from hunting and foraging to industrial labor and white-collar jobs. According to the census, the tribal literacy rate is 47.1 percent. The Government of India has designated seventy-five communities among the STs as Primitive Tribal Groups (PTGs), for whose development specific microprojects have been designed and implemented. Despite constitutional protection, Scheduled Tribes in India are still impoverished and marginalized.

TRIBES, INTERNATIONAL CONVENTIONS, AND HUMAN RIGHTS
Many tribes have come to symbolize the most victimized segments of societies. It is a strange paradox that although they inhabit the most resource-rich regions of the world, many of them are in a state of impoverishment. They are the most severely affected victims of induced development, such as the establishment of mega-hydroelectric projects, conservation through parks, sanctuaries and bio-reserves, mining and allied activities, urbanization and industrialization, ecotourism projects, and so on. As John Bodley notes in his 1988 study, these activities cause involuntary displacement, alienation from natural resources, cultural disorganization, and disengagement with the intense community life, eventually pushing them into abject poverty and squarior. Their problems are compounded by the penetrating regime of globalization and a competitive market economy. The Jarawa of the Andaman Islands, the Yanomami group of tribes of South America, and others are now vulnerable to new diseases like measles and mumps because of their exposure to the people outside their habitat.

Concern for the plight of the tribes and indigenous peoples is growing in many quarters, and efforts are being made to protect them and preserve their cultural heritage. The International Decade of the World’s Indigenous People (1995–2004), declared by the United Nations; the International Labor Organization conventions 107 (1957) and 169 (1989); and the Convention on Biological Diversity (1992) have made special provisions for protecting the civil and political rights of the tribes and indigenous people. Tribal empowerment and participatory development have become buzzwords in the field of tribal development, and efforts are being made to reverse the trend of marginalization of tribes all over the world.

TRIGUEÑO
The term *trigueño* is derived from *trigo* (wheat) and literally means “wheat-colored.” The term seems to have gained currency in twentieth-century Puerto Rico and
elsewhere in Spanish-speaking Latin America (Argentina, Bolivia, Cuba, the Dominican Republic, Ecuador, Mexico, Peru, and Venezuela) to describe people with a tan or brown skin tone (piel morena). However, its meaning and social uses contain the same ambiguities inherent in all so-called race-related concepts as race is not an objective fact of nature but what might be called a social fact, subject to power dynamics and the social hierarchies of racism. Thus, in the Hispanic Caribbean, trigueño is also deployed as a euphemism for Negro (black). This is to avoid the pejorative connotations derived from the association of Negro with slave status. This use of trigueño is similar to the more old-fashioned term de color (colored), which is also used euphemistically to refer to black people. However, trigueño can also be used in Puerto Rico and in Cuba to describe a light-skinned person with a slightly tanned complexion.

The term therefore covers a wide variety of skin-color types: black, lighter than black, or darker than white. Which meaning is ascribed will depend on factors such as who says it, in what context, in what country, and how the person’s skin color is perceived in combination with other phenotypic markers. In Puerto Rico, for example, two individuals might have the same dark-brown skin, but if one has kinky hair and the other has straight hair, the person with straight hair will probably be called Indio (Indian) and the person with coiled hair trigueño.

The application of trigueño also can be influenced by the relationship between the person describing and the one who is being described and by their perception of blackness. For example, if two people do not know each other well, one person might describe a black person as a trigueño(a) for reasons of social etiquette. This “polite” euphemistic use presumes and does not challenge the negative connotations associated with Negro. People who proudly assert a black identity, therefore, might dislike other people using trigueño to describe them or others because it assumes their blackness should be hidden or whitened by this euphemistic expression.

In a different context, a person might use trigueño to describe someone considered neither black nor white. In such cases, applying trigueño is not necessarily informed by the belief that Negro is offensive. Rather, it shows an attempt to make an accurate description in a social context where trigueño is associated with a mixed-race individual and is set apart from other racial types that are understood as less hybrid, such as blanco or Negro.

Depending on who uses it, how, and to whom they apply it, therefore, the use of trigueño can be interpreted as a polite gesture, as the sign of a condescending attitude toward black people, or as a phenotypic marker of racial mixture that lies somewhere between the white and black poles of a racial continuum.

TRIERAL COMMISSION

Constituted of over three hundred leading politicians, businesspeople, and intellectuals from Western Europe, Japan, and North America, the Trilateral Commission was founded in 1973 by David Rockefeller, then chairman of Chase Manhattan Bank. Rockefeller had called for the establishment of the organization in a 1972 speech before the Bilderberg Group, a secretive post–World War II (1939–1945) discussion forum regularly attended by heads of state and other “influentials” from Europe and the United States.

In the wake of the collapse of the Bretton Woods system in the early 1970s, many members of the Bilderberg Group were concerned that the unilateralist foreign and economic policies of U.S. President Richard Nixon (1913–1994) were jeopardizing the cold war liberal order. Launched in 1946, the system was constituted by a set of multilaterally agreed-upon rules for regulating commercial and financial relations among the world’s most powerful states. Given the rise of Japan and West Germany as economic powers and the decreased capacity of the U.S. state to direct world affairs, they feared a return to the “beggar-thy-neighbor” interstate rivalry that had characterized the interwar years. As such, they believed that the responsibility to lead would now have to be shared among the advanced nations.

The Trilateral Commission was established to bring together leading intellectuals and policymakers from the United States, Europe, and Japan in order to forge among them such consensus as necessary for the successful “collective management” of the world economy. The chairmen of the Commission detailed the group’s philosophy of international cooperation in the foreword to a collection of the Commission’s early Triangle Papers (task force reports). There they suggested that Trilateral cooperation...
should be based not on “coercion and arm-twisting, but on the mutuality of interest and indeed on the longer-term interest of mankind” (Berthoin, Smith, and Watanabe 1977, p. viii).

The first public statement of the Trilateral Commission was issued in Tokyo in October 1973. It spoke of both the “new problems” confronting nation-states under conditions of complex interdependency and the “special responsibility” of the Trilateral countries for “developing effective cooperation, both in their own interests, and in those of the rest of the world.” Moreover, it set out the agreed-upon rules and procedures to govern the official interactions between Trilateral countries. It stipulated that they should work with each other “on the basis of equality” and avoid any such unilateral interaction as would be “incompatible with their interdependence.” In closing, it elaborated the “creative role” of the Commission in generating consensus among its constituent states through a “sustained process of consultation and mutual education” (Trilateral Commission 1973, pp. 1–2).

The highlight of the Trilateral Commission’s year is its annual plenary meeting. These sessions are supposed to build collegiality among the members, allowing them to develop trust in each other and familiarity with each other’s customs. Among the agenda items generally discussed at plenaries are the reports of special “task forces,” directions in future research, and possible new members. The preparation of task force reports is an essential part of Commission activity. Task forces focus on a variety of topics, from such immediate concerns as currency market fluctuations and arms control, to more long-term issues like the impact of technological transformation on world affairs.

Founded as a nonpermanent organization, the Trilateral Commission must regularly meet to review its purposes and determine if it wishes to continue operation. Such reviews happen every three years (every “triennium,” in the official jargon). The business of each region is steered by a chairperson, with daily activities managed by a director. An Executive Committee provides overall direction and initiates the Commission’s policy studies. There is also a Program Advisory Board that advises the director and regional chairpersons on policy studies.

Criticisms of the Trilateral Commission have been issued from both the left and the right. Left-wing critics see the organization as a booster club for transnational elite interests. Stephen Gill (1990), for example, argues that the Commission is an “ideological apparatus” developed by a transnational capitalist class in response to the general crisis of American hegemony presented by the end of the Bretton Woods system.

Critics on the extreme right, like Lyndon LaRouche, argue that the Trilateral Commission is part of a global network of “Anglo-American Liberal Establishment” organizations that constitute the “shadow government” of the United States. In 1980 LaRouche accused George W. Bush of being an agent of the Trilateral Commission in order to help Ronald Reagan (1911–2004) win the Republican presidential nomination (see Berlet and Lyons 2000).

Large portions of the American delegations to the Trilateral Commission are often drawn from the political elite. Many of the original U.S. delegation went on to serve in the Jimmy Carter administration (1977–1981), including President Carter himself, Vice President Walter Mondale, security advisor Zbigniew Brzezinski, and Secretary of State Cyrus Vance (1917–2002). In 2007, Vice President Dick Cheney was also a member. Representatives of the U.S. delegation are often also members of the Council on Foreign Relations, an influential Washington, D.C., think tank.

TRILATERALISM

Unlike related terms such as multilateralism, internationalism, or unilateralism, the term trilateralism carries with it little connotation of an underlying methodological or ideological approach to managing international disputes or negotiations, though this was not always the case. At its most basic level, trilateralism is simply a way to describe more specifically international interaction among three entities (usually nation-states) so as to differentiate between bilateral or multilateral formats when discussing trade, security, or other international policy issues. There are several examples of such arrangements, including the trilateral negotiation in the early 1990s over the North American Free Trade Agreement (NAFTA) by the United
Triumphalism

States, Canada, and Mexico, and a formal series of meetings by South Korea, Japan, and the United States over four years ending in 2003 regarding foreign policy coordination vis-à-vis North Korea (known as the Trilateral Coordination and Oversight Group, or TCOG).

The use of the term trilateral to describe a specific subset of multilateral events essentially began in the 1970s, due primarily to the establishment of the Trilateral Commission by citizens of North America (United States and Canada), Western Europe, and Japan. At this time, trilateralism did have an ideological connotation, as it became closely associated with the commission’s core emphasis on reaching beyond the established transatlantic relationships to draw Japan into a three-region coalition of so-called industrial democracies whose political and corporate elite would work together to promote liberalism, open markets, and economic interdependence. To critics, these trilateralists were trying to dominate the global economy and to exploit weaker nations, whereas proponents viewed this as a well-intentioned effort to develop a broader coalition of leaders focused on mitigating international conflict and isolationism by promoting common interests and values.

As economic interdependence accelerated and blossomed into globalization throughout the 1980s and 1990s, however, many new potential coalition partners emerged, such as South Korea, Mexico, Singapore, and Taiwan, thereby introducing greater complexity and diluting the broader triangular image. The collapse of the Soviet Union in 1991 accelerated this trend. Trilateralism lost its ideological flavor, but it endured as a convenient way to describe a variety of new three-way interactions. An early post-Soviet example is the so-called Weimar Triangle, launched in Weimar, Germany, in 1991 by the foreign ministers of Germany, France, and Poland as a loose alliance to promote Poland’s emergence from Communist rule.

Trilateralism coexists with other dialogue formats because it offers some advantages in certain situations. For international trade negotiations, such as NAFTA, three-way agreements can be easier for governments to navigate compared to broader multilateral initiatives that must reconcile the nations’ conflicting interests and proposals; yet they can offer greater benefits or efficiency than a collective set of three bilateral agreements. In addition to formal negotiating forums, trilateralism can describe less structured gatherings of national representatives dedicated to issues of common concern. The Weimar Triangle is one example, but there are many other groups of countries that promote trilateral dialogue about such issues as trade, investment, immigration, transportation, environment, and security, including the Trilateral Wadden Sea Cooperation group involving the Netherlands, Germany, and Denmark (starting in 1978), as well as tripartite cooperation by Japan, South Korea, and China, starting around 1999, which promotes a broad agenda of regional economic, social, and political initiatives. Small multilateral gatherings of more than three entities (but usually not more than five or six) can be considered minilateral meetings and offer some of the same advantages as trilateral forums.

Occasionally these trilateral meetings become institutionalized and self-sustaining; other trilateral experiments are more beholden to particular founding individuals or diplomatic moods and consequently their relevance fluctuates over time (or they disappear altogether). The TCOG, for example, was an active forum for policy coordination vis-à-vis North Korea for almost four years, but it essentially dissolved when the policy approaches of three countries diverged too widely following leadership changes.

Another use of trilateralism is as an attempt by three states or other entities to present a united front on a given issue of collective concern or to otherwise form a de facto caucus within a larger multilateral organization. Macedonia, Croatia, and Albania, for example, began formal collaboration in 2003 to promote their collective entry into the North Atlantic Treaty Organization (NATO) and the European Union (EU). Finally, trilateral meetings are also sometimes arranged as a means of formal dispute resolution, whereby one participant acts as a mediator or facilitator between two conflicting parties. A well-known example is the negotiation of the Camp David Accords in 1978 by U.S. President Jimmy Carter, Egyptian President Anwar Sadat, and Israeli Prime Minister Menachem Begin.

TRIUMPHALISM

Triumphalism consists of the warrantless assertions that the decline or defeat of an adversary is caused by an antagonist and that the antagonist’s success is a sign of superior virtue. In the post–World War II period, for instance, the
political and economic collapse of the Soviet empire is often attributed to a competitive loss to Western European and North American capitalist powers. The fall of the Soviet Union is alleged proof of the superiority of those economic and political institutions over their Soviet counterparts.

Triumphalism is a combination of two mistaken assertions. The first assertion, that the defeat of one is due to the effort of another, is what classical rhetoricians since Aristotle have called a fallible sign. Not only is the assertion open to refutation, but its certainty can never be reliably established beyond doubt. The second assertion, that the adversary’s defeat establishes the virtue of the victor, is a value judgment. As such, no credible facts can be derived from the perspectives of the victor or the loser that are not tainted by their interests. Thus facts cannot validate values, only facts.

The German sociologist and economist Max Weber is perhaps most responsible in the social sciences for stressing the ultimate dependence of the constitution and relevance of facts on values. His student, the Hungarian sociologist Karl Mannheim, showed how class interests were particularly important in forming worldviews whereby both values and facts attained cultural significance. In modern philosophy the American Thomas Kuhn’s argument that knowledge is normative and writer Hilary Putnam’s (b. 1926) insistence on the inseparability of judgments about facts and values have contributed additional support to a more general view that there can be no such thing as a value-free estimation of the world and its virtues. This position would view triumphalism as logically untenable.

If one starts with individual values, some difficulties can be avoided. Take the phenomenon of increased economic inequality in post-Soviet Russia. A believer in competitive capitalism valuing individual freedom in economic pursuits, for instance, would find growing economic inequality in post-Soviet Russia perhaps a necessary condition for the success of an enterprising minority. A socialist from the Soviet era, in contrast, would find the growth in economic inequality in post-Soviet society iniquitous. Thus in this case the fact of increased economic inequality in post-Soviet Russia takes on a differential significance, based upon one’s basic values.

There are, however, more difficult scenarios. Suppose two persons or groups claim to agree on basic values but do not count as significant the same facts. In the United States people for and against therapeutic abortions value the sanctity of human life. The antiabortionists count fetal deaths as the indispensable marker for valuing human life. The pro-abortionists count the health of the pregnant woman as the vital measure of human well-being. Neither accepts the facts of the other as valid counters in valuing the sanctity of human life.

These two instances do not exhaust the logical possibilities of the problems entailed in assessing facts via values and vice versa. They do suggest, however, how triumphalism as a theoretical practice is undercut by its reliance on unwarranted assertions on both sides of a given fact-value equation.

TROTSKY, LEON
1879–1940

Leon Trotsky (Lev Davidovich Trotsky [Bronshtein]) was a leading Russian revolutionary. Born into a Jewish farming family in present-day Ukraine, Trotsky became a Marxist publicist and organizer in the 1890s. During
Russia's 1905 Revolution, he became chairman of the St. Petersburg Soviet of Workers' Deputies just before its suppression by the tsarist government. Forced to flee Russia, he spent the next several years as a journalist in Europe.

After 1917's February Revolution overthrew the tsarist regime, Trotsky returned to Russia. Despite fifteen years of disputes with Vladimir Lenin, Trotsky now found their views congruent, and joined Lenin's Bolsheviks to help lead the October coup d'etat that overthrew Russia's provisional government. Trotsky served briefly as Soviet foreign minister before shifting in spring 1918 to building the Soviet military to fight the Russian civil war. After the Red Army's 1920 victory, Trotsky struggled against other Bolsheviks to take the ailing Lenin's place as head of the Soviet Union. For some historically conscious Bolsheviks, Trotsky's talent, military authority, and arrogance raised the specter of a new Bonaparte; a coalition of enemies, led by Joseph Stalin, first removed him from power then exiled him in 1929.

Trotsky produced a remarkable amount of work, including history, military theory, and even literary criticism, but his key contribution is his concept of permanent revolution (perhaps more aptly termed uninterrupted revolution). According to classical Marxism, proletarian revolution can take place only after a successful bourgeois revolution and the consequent long-term development of capitalism create material abundance, socioeconomic polarization, and a self-conscious working class. After the 1905 Revolution, however, Trotsky suggested that in Russia, the bourgeoisie alone was too weak to overthrow the autocracy and establish bourgeois capitalism. This created an opportunity for the proletariat to hijack the bourgeois revolution, by collaborating with the bourgeoisie to overthrow the tsarist regime, then immediately destroying the bourgeoisie and establishing a proletarian government—precisely what Lenin and Trotsky later did in 1917. Though Trotsky's theory had a specifically Russian context, he noted its applicability to other backward societies.

Russian backwardness was, however, a double-edged sword. While it allowed direct transition from bourgeois to proletarian revolution, it produced a socialist regime in an underdeveloped country. Without accompanying revolutions in industrially advanced countries, the new Soviet state was vulnerable. This led Trotsky after 1917 to promote revolution abroad to protect Soviet Russia, a stance Stalin distorted. Painting Trotsky as pessimistic about Soviet prospects, Stalin used nascent Soviet nationalism against him. Soviet backwardness also led Trotsky to push industrialization, if necessary at the peasantry's expense. Though Stalin attacked this policy during the struggle for power, he adopted it upon consolidating victory.

Trotsky's theoretical work continued in exile. Trotsky did not attribute his defeat to Stalin, who he dismissed as a nonentity, but instead to Russian backwardness. Material want and a scarcity of class-conscious workers, Trotsky argued, created the conditions for the ascendance of the Soviet bureaucracy, which employed Stalin as a tool to solidify its own position. In analyzing the bureaucracy, Trotsky anticipated later criticisms that suggested that Marxist revolutions merely substituted a new exploitative ruling class for the old one. Trotsky, however, did not see the Soviet bureaucracy as a class, for that would mean that Russia's proletarian revolution had failed. Though deformed and twisted by the bureaucracy, the Soviet Union remained for Trotsky a genuine workers' state, the fruit of a true proletarian revolution.

Trotsky's opposition to Stalin led to his assassination in 1940 by a Stalinist agent in Mexico City. He was a nonperson for the rest of the Soviet Union's existence, his achievements expunged from the historical record. Elsewhere, however, his charisma, anti-Stalinism, rhetorical flair, and reputation as the ne plus ultra of the revolutionary left ensured that Trotskyism remained an important force on the far left.

TROUBLES, THE

SEE Irish Republican Army.
TROUILLOT, MICHEL-ROLPH
1949–

Few scholars actually practice the discursively much-touted interdisciplinarity of early-twenty-first-century social science. Michel-Rolph Trouillot, an anthropologist whose intellectual homes are history and philosophy, is one. Haitian by birth and in sensibility, he came to the United States by chance but chose to become a Caribbeaniast. His work on Dominica and Haiti, though steeped in the details of time, place, event, and person that some carelessly dub local color, embraces the Americas and the world through a radical yet discerning critique of the West and capitalism. Some fifty publications, in three languages and spanning the usual text types, display Trouillot’s unusual capacities for sophisticated, politically engaged theorizing and careful empirical observation. Trouillot’s conference presentations, undergraduate courses, graduate seminars, editing of scholarly book series or journals, and informal conversations have also been important pathways for his critique’s cumulative movements.

FAMILY HISTORY AND EDUCATION

Since Haiti’s independence in 1804, many Haitian families have had black and mulatto wings with rural or urban staves in the peasantry, the middle and working classes, and the elite. By the mid-twentieth century, the black middle class Trouillots of Port-au-Prince included intellectually inquisitive and politically active professionals. Trouillot’s father, attorney Ernest Trouillot (1922–1987), deftly practiced the historian’s craft as an avocation. His paternal uncle, Hénock Trouillot (1923–1988), arguably Haiti’s most prolific, subtle, and influential Noiriste historian, was a professor and for many years director of the Archives Nationales d’Haïti. Michel-Rolph, born on November 26, 1949, the second of four children, grew up in a household full of ideas and lively argument about things of this world—literature, science, art, economics, music, politics—and about how the past shapes those things in the present.

At age five, Trouillot enrolled in Port-au-Prince’s Petit Séminaire Collège Saint-Martial and, under the tutelage of its progressive Pères du Saint-Esprit, completed the Baccalaureate II (Philosophy) in 1968. In the same year, he began courses at L’École Normale Supérieure. However, the Duvalier dictatorship’s escalating repression of student activists compelled Trouillot to join hundreds of young compatriots who sought refuge in New York City, which was then host to the Haitian Diaspora’s largest population. Trouillot received a bachelor’s degree (BA) in Caribbean history and culture at Brooklyn College, City University of New York (CUNY) in 1978, driving cabs to pay for his education and support his wife and children. He devoted spare time (not free, he would emphasize) to reading, Haitian Diaspora politics, and writing poetry and journalism. In 1977 he completed his first book, Ti difé boulé sou istoua Ayiti, an incisive Marxist analysis of the Haitian Revolution and politico-ideological developments immediately after Haitian independence, presented in the playful style of Haitian Creole dialogues. At the same time, he initiated research for two papers on coffee production in Saint-Domingue/Haiti that would alter Caribbeaniasts’ thinking about the sociology, economics, and politics of slavery and freedom around the turn of the nineteenth century.

In 1978, anthropologists Sidney W. Mintz and Richard Price recruited Trouillot for the Johns Hopkins University Program in Atlantic History and Culture, and he completed a PhD in anthropology in 1985. By that time, Trouillot was already an assistant professor at Duke University (1983–1988), working closely with colleagues in other departments to establish the University’s Caribbean Studies program and planning revisions of his dissertation, which became his second book, Peasants and Capital (1988), a detailed ethnographic and historical study of how Dominica’s peasantry copes with the global banana industry. Trouillot subsequently returned to Johns Hopkins, first as associate professor, then as Krieger/Eisenhower Professor of Anthropology and founding director of the Institute for Global Studies in Culture, History, and Power. Since 1998, he has been professor of anthropology at The University of Chicago.

WORK AND INFLUENCE

Haitian relatives and intellectuals aside, Karl Marx is Trouillot’s main source of inspiration in the study of world history. However, his work also reflects lessons learned from an international, multidisciplinary cohort of predecessors including Mintz, Eric R. Wolf, Price, David W. Cohen, Immanuel Wallerstein, Fernando Braudel, C. L. R. James, Antonio Gramsci, Jean-François Lyotard, Michel de Certeau, and Hayden White. This list omits Trouillot’s contemporaries, diversely self-identified interlocutors in the social sciences and philosophy whose influences he generously acknowledges in books and articles. He also constructively appraises their scholarship in reviews or review essays, and subjects it to illuminating commentary in symposia and workshops.

Synthesizing diverse lineages of ideas, Trouillot routinely unsettles taken-for-granted dichotomies concerning concepts and data in research on political economy, society, and culture by historicizing and contextualizing them. Nevertheless, three binary oppositions establish a purchase for understanding the scope and depth of his work:
stasis/movement or flow, agency/contingency, and articulation/separation or plural integration. Trouillot relentlessly zigzags across the boundaries of these concepts to gauge relations of dominance and determination between the canalizing effects of material conditions and the creative potential of structures and processes of signification.

Polemics against empiricism, parochialism (e.g., exceptionalism, individualism, and subjectivism) and idealist or realist cultural approaches to symbolism (including identity politics) animate Trouillot’s work. He is especially critical of the common, though naïve, assumption that the purposes of study, objects of observation (or units of description and analysis), and sites of inquiry are homologous. Carefully crafted operational definitions of concepts and categories for a research project, one imagines, might overcome naïveté. Yet Trouillot rejects operational definitions, insisting that they fetter serious investigation of the play of concepts and categories, and the search for relevant evidence.

These two moves puzzle methodologically oriented scholars who view theory as an indispensable guide to empirical research, but do not consider theory construction its sole or primary goal. The point holds even for core subject matters of Trouillot’s best-known works. One example is the concept of the State, particularly in countries once called third world or peripheral but now forming the Global South. Another is the productivity of varied forms of power in history that precipitates privileged narrators along with mentions and silences in narratives about selected information from the past. Likewise, Trouillot had probed the savage slot by placing the pre-suppositions, propositions, and consequences of anthropology’s mission to study “primitive” peoples, cultures, and societies in a world-historical context. Therefore, he responds with a knowing smile to the malaise among anthropologists concerning epistemology, ethnographic authority, and incursions into their traditional turf, fieldwork. As disciplinary boundaries crumble and global flows accelerate, Trouillot laconically proclaims that academic disciplines are what their practitioners do. Scholars who have learned from his work await its next movements.

TRUDEAU, PIERRE ELLIOT
SEE Quebecois Movement.

TRUMAN, HARRY S.
1884–1972
Harry S. Truman was the thirty-third president of the United States of America. He was born on May 8, 1884, in Lamar, Missouri, and died on December 26, 1972, in Kansas City, Missouri. His middle initial, S, does not begin a middle name because of a family disagreement over whether his middle name should be “Solomon” or “Shipp(e).” Truman’s family moved to Independence, Missouri, in 1890. After graduating from high school in 1901, Truman worked at several clerical jobs and in 1905 joined the Missouri National Guard. He worked at his family’s farm from 1906 until 1916.

During World War I, Truman served as an artillery captain in France. Truman was respected by his troops for his bravery in combat and leadership ability. After he returned to Missouri, Truman married Elizabeth “Bess” Wallace. Truman and an army friend, Edward Jacobson, opened a haberdashery in Kansas City. It was a popular place for veterans to socialize, but the business suffered during the 1921–1922 recession and went bankrupt.

James Pendergast, a veteran of Truman’s artillery unit, persuaded his uncle, machine boss Tom Pendergast, to ask Truman to run for a seat on the county “court,” actually a public works commission. With the support of the Pendergast machine, Truman was elected as a Democrat to the Jackson County court in 1922, 1926, and 1930. Despite his affiliation with the Pendergast machine, Truman earned a reputation for honesty and efficiency, especially in the construction of new roads and a new courthouse. He accepted Tom Pendergast’s offer to run for the U.S. Senate and was elected in 1934.

Upon his arrival in the Senate in 1935, Truman was initially dismissed by his colleagues as the “Senator from Pendergast” because of his association with the notorious political machine. Truman was frustrated and disappointed by President Franklin D. Roosevelt’s apparent indifference and occasional hostility toward him. While generally supporting New Deal legislation, Truman also backed Roosevelt’s failed, controversial “court-packing” bill, higher defense spending, military aid to Great Britain, and military conscription before the United States entered World War II. At Truman’s suggestion, the Senate created a special committee to investigate waste, fraud, and mismanagement in defense contracts and appointed Truman as its chairman. The Truman Committee saved $11 billion in defense spending and made Truman a respected national political figure.

By 1944 a growing number of Democratic politicians and campaign contributors wanted Roosevelt to replace Vice President Henry A. Wallace with Truman as his running mate in the 1944 presidential election. Truman reluctantly accepted Roosevelt’s offer to be his running mate. During and after the 1944 election, Truman was concerned that the ailing Roosevelt rarely consulted him and did not confer with him about major war policies and postwar plans. Truman’s brief vice presidency ended with Roosevelt’s death on April 12, 1945.

TRUMAN’S PRESIDENCY
Truman’s first few months as president were a whirlwind of major world events and presidential decisions. Germany surrendered on May 7, 1945. From July 17 until August 2, Truman conferred with Winston Churchill and Joseph Stalin in Potsdam to determine the postwar occupation of Germany and the trial arrangements for Nazi war criminals. One week later, Truman ordered the dropping of atomic bombs on Japan. Japan formally surrendered on September 2. On September 8, Truman ordered American troops to be stationed in South Korea.

During his first year as president, Truman also confronted labor disputes, inflation, and public demands for a more rapid demobilization of troops and reconversion to a civilian economy. Truman became known for his blunt rhetoric and unequivocal decision-making style, epitomized by the catchphrases “The Buck Stops Here” and “Give ‘em Hell.” Nonetheless, Truman’s declining public approval ratings and the public perception of his inferiority to Roosevelt helped the Republicans to win control of Congress in 1946.

With regard to foreign and defense policies, Truman had a fairly productive and effective relationship with the Republican-controlled 80th Congress. Truman and Congress enacted the Marshall Plan for the economic reconstruction of Western Europe and a similar plan for Japan, sent military and economic aid for the Greek and Turkish governments fighting communist aggression, reorganized the Department of Defense, and established the foundation of the North Atlantic Treaty Organization (NATO) for the collective security of Western Europe.

In the area of domestic policy, however, Truman often had disagreements with Republicans and conservative Southern Democrats in Congress. In 1947 the Taft-Hartley Act, which reduced the legal powers and privileges of labor unions, became law over Truman’s veto. Southern Democrats and some Republicans rejected Truman’s civil rights legislation for African Americans.
Most Republicans in Congress disagreed with Truman on tax, housing, price control, and agricultural issues. Truman’s campaign in the 1948 presidential election repeatedly denounced the “do-nothing Republican 80th Congress” on domestic issues and implicitly linked it to Governor Thomas E. Dewey of New York, the moderately liberal Republican presidential nominee. Friendly crowds encouraged Truman to “give ’em hell.” Meanwhile, the Democratic Party splintered further. The most anti-civil rights Southern Democrats supported Governor J. Strom Thurmond of South Carolina as the presidential nominee of the States Rights Democrats, or “Dixiecrat” party. Anti-cold war liberals and leftists supported the Progressive Party’s presidential nominee, Henry A. Wallace.

With a comfortable lead in public opinion polls, Dewey avoided sounding antagonistic toward Truman and addressing specific issues that might reveal his differences with more conservative Republicans in Congress. Major newspapers and magazines predicted Dewey’s victory and speculated on his future policies and cabinet appointments. The Chicago Tribune’s top headline on Election Day famously announced, “Dewey Defeats Truman.” Nonetheless, Truman won an upset victory. The Democrats also won control of Congress.

In his 1949 message to Congress, Truman proposed what he called “a Fair Deal for all Americans.” His major policy proposals included civil rights, national health insurance, and repeal of the Taft-Hartley Act. Except for the Housing Act of 1949, Congress rejected all of the major Fair Deal legislation.

Republicans charged that the Truman and Roosevelt administrations had failed or refused to uncover and prevent communist influence on American foreign and defense policies; in response, Truman created loyalty review boards to find communists in the federal government, especially the state department. The Truman administration’s reputation was also tarnished by congressional and media investigations of corruption on the part of some officials. These issues were overshadowed, however, by the communist takeover of mainland China in 1949, the Soviet detonation of an atomic bomb, and the outbreak of the Korean War in 1950.

Truman secured a decision from the United Nations (UN) authorizing the United States and other UN members to support South Korea. He appointed General Douglas MacArthur commander of the American and other UN forces in Korea. After MacArthur publicly defied Truman’s strategy of limiting the war to Korea and avoiding a war with China, Truman removed MacArthur from command. Truman’s removal of MacArthur and the ensuing stalemate in the Korean War proved to be unpopular. Truman spent the remainder of his presidency defending his policies in Korea and supporting the Democratic presidential campaign of Illinois governor Adlai Stevenson in 1952.

After Republican presidential nominee Dwight D. Eisenhower easily defeated Stevenson, Truman spent the early years of his retirement supervising his presidential library in Independence, Missouri, and writing his memoirs. On December 26, 1972, Truman died of complications from pneumonia in a Kansas City hospital. During his retirement and after his death, Truman’s historical reputation steadily improved, especially for his integrity and major foreign policy decisions.

TRUST

Trust, the general sense of well-being in relation to one’s self and toward others, is an essential attribute of human character as well as of interpersonal interaction. The attainment of a sense of trust has long been thought by ego psychologists to be the first human developmental task and is based largely on the infant’s growing expectation that the mothering figure will become a constant source of nurturing and satisfaction in the individual’s life. Good nurturing thus disposes the individual to anticipate positive encounters with the environment and with other persons.

There is common agreement that trust is an essential factor in successful social environments and interactions. Persons need to feel secure in their expectations for good outcomes as they go about their daily lives. For instance, they need to assume that an elevator is functioning normally, that they will be understood linguistically if they cry for help, and that a medical professional will try to do them good rather than harm. So important is what could be called “background trust” that experimentally breaching it, as sociologist Harold Garfinkel has shown, by speaking nonsense when a person asks for directions or help, causes subjects to become extremely angry and anxious. If one has a flat tire, and the experimenter replies to
a call for help by asking what a tire is, rage on the subject’s part is sure to follow. Hence there is strong reason to think that trust is an interaction imperative, up to and including dealing with one’s enemies, as the history of the cold war suggests.

The greater the degree of trust in social transactions, it is believed, the more optimal are the satisfactions for participants. Relations between members of households and kin networks, for instance, are typically characterized as high in trust, and it is notable how solutions to the most difficult problems of human dependency, such as infancy, old age, and disability, are undertaken at great sacrifice within their confines. Trustworthy expectations also flow through social networks such that they are an important source of economic opportunities such as job finding and job getting.

Trust and exchange, used here in the broadest sense, are intimately related. Exchange creates trust, and trust facilitates exchange. Among members of small-scale societies, gift giving creates the necessity of reciprocity and generates in the giver the expectation of being a receiver and thus a beneficiary of a gift in a future transaction. Bonds of mutual expectation are formed and can often support the exchange of purely economic goods, as the classic investigation of anthropologist Bronislaw Malinowski (1884–1942) among the Trobriand Islanders of the Pacific a century ago showed.

The depth of trust among participants also affects exchanges in markets. At minimum, most economists recognize trust as a helpful externality: that is, trust is a noneconomic element that improves economic efficiency by increasing the speed of transaction and limiting the need for costly conditions to ensure mutual compliance. Its absence increases economic risk and may foster opportunism among buyers and sellers that limits the scope of market transactions. Lack of trust between producers and suppliers has been argued as a primary motivation for the growth of large, vertically integrated industrial firms. If firms cannot trust their suppliers to deliver quality goods in a timely and cost-effective fashion, they reason it is better to produce the goods internally or purchase the supplying firm outright.

On the other hand, trust, it has been argued, can be misplaced. Exclusive trust in kin or in personal and social networks often signifies lack of trust in other persons, networks, and institutions outside their purview. This difference toward others can create economic and political troubles. Politically, Robert D. Putnam has argued, for instance, that trust is an indispensable good for building a successful civil society and, by implication, a functioning democracy. In a world economy dominated by large corporations, the temporary advantages afforded by a high degree of internal trust found among families and kin groups that stimulate high levels of personal dedication, income pooling, and personal sacrifice can become overwhelmed by such problems as small firm size, stunted organizational growth, and lack of access to capital markets for expansion. If mistrust in the face of outsiders in markets leads to out-and-out hostility, deviant economic combinations, such as the mafia and what Max Weber (1864–1920) called “pariah capitalism,” can arise. A market where neither the expectation nor the reality of fair treatment, both reliant on background trust, is met tends to founder and shrink. Moreover, exploitation of others outside the bounds of exclusive trust becomes highly likely.

Exclusive bonds of trust need not be overtly hostile to be exploitative. Cartels and trusts, historic fetters on economic efficiency, are precisely the products of relations of trust developed among nominally competing firms. Through the reciprocal exchange of information, favors, and market opportunities, they effectively charge a tax on their transactions with other buyers and sellers outside their circle.

As world society and the world economy become more integrated, globalized in a word, the need for, as well as evidence of, a more generalized interpersonal trust have been noted. Mass travel and migration, unprecedented collective reliance on large bureaucratic organizations for all kinds of commodities and services, and the rise of communication and information technologies necessitate increased contact with impersonal, anonymous persons, providers, and interlocutors. The sense of well-being and the expectation of gratification embodied in the concept of trust take on even greater importance. There are many instances in which this sense of globalized background trust can be observed, from the casual use of the credit card to the ease with which one can trade, borrow, and travel in ever grander geographical and social spaces. Inside large organizations, the same expectations of good interactions are created through rewards and training, though employee trust can be lost easily through the abuses of hierarchy and corporate economic power.

TRUTH, SOJOURNER

c. 1797–1883

Sojourner Truth was born a slave in Ulster County, New York. Her masters at birth were the Hardenburgh family, descendents of Dutch “patroon” planters, and she was named Isabella Baumfree at birth. During her lifetime she was sold several times, married Thomas DuMont, another slave, and had at least four children with him. In 1827 New York freed all remaining slaves, but Isabella had already left her owners. After the abolition of slavery, she successfully sued her former owners to obtain the freedom of one of her children, whom they had transferred to Alabama.

The 1830s were a time of great religious ferment, called the Second Great Awakening. Isabella was caught up in the movement, and she traveled around the northeast and settled in several religious communes. It was about this time that she began calling herself Sojourner Truth and became an itinerant preacher.

In the 1840s she became active in the abolitionist movement, and she worked with many abolitionist leaders such as Frederick Douglass (1817–1895) and William Lloyd Garrison (1805–1879). She was in great demand as a speaker, and her memoir *The Narrative of Sojourner Truth, a Northern Slave*, was dictated to and edited by abolitionist author Harriet Beecher Stowe (1811–1896).

Sojourner Truth also became involved in women’s rights issues. Like many abolitionists, she saw a connection between the issues of women’s liberation and freedom for blacks. Her most famous speech, “Ain’t I A Woman?,” was delivered at a women’s rights conference in 1851. The speech was transcribed by another woman abolitionist, Frances Gage, who published it almost thirty years later. Gage’s text is the only record of Sojourner Truth’s oratorical style, and it is written in nonstandard English. It is unclear if that is really the way Sojourner Truth spoke. Contemporaries, both black and white, always described her as a riveting speaker, and nobody ever suggested that her English was poor or difficult to understand. Nonetheless, the speech as transcribed shows some of the power of Sojourner Truth’s oratory: the biblical or theological arguments mixed with homely, rural simile, the chatty tone, the repetition of “and ain’t I a woman?” and other rhetorical elements that have made this speech a classic of early feminism.

When the Civil War (1861–1865) broke out, Sojourner Truth worked for better conditions for blacks in the Union military and against segregation in northern cities. After the war she called for the establishment of a “Negro state” in the west. She also supported the Freedman’s Bureau and tried to help black war refugees and the newly freed people in the South find jobs and housing. She continued to work for women’s rights, civil rights for blacks, and temperance (laws restricting alcohol consumption) until her death in 1883.

Sojourner Truth is important because she helped set the terms of reference for the debate over slavery, civil rights for blacks after the Civil War, and women’s rights in the United States in the mid-nineteenth century. She is probably as important a figure as any of the other well-known abolitionists—Douglass, Garrison, Beecher Stowe—especially because as a black woman she has inherent credibility on both black and women’s issues. She is also important as an example of a little-appreciated phenomenon, the link between Protestant evangelical Christianity, abolitionism, and women’s liberation. It is important to realize that in the middle of the 1800s, evangelical Christians were more likely to be radicals than conservatives. Finally, she deserves attention because of her lively speaking style. There is a reason that she stood out as a speaker and sold many books in that era, so well provided with great speakers and writers.

TRUTH AND RECONCILIATION COMMISSIONS

Many countries with histories of widespread human rights abuses in the past have turned to truth and reconciliation commissions as an institutional solution to the problem of
transitional justice and attempted democratization. Although these commissions take many forms—and are assigned a variety of mandates—each is charged with investigating the truth of past events with the hope that knowing about the truth will contribute to “reconciliation.” Roughly two dozen such commissions have been created (including one in Greensboro, North Carolina, charged with discovering the truth of what happened during a political riot in 1979). Many more such tribunals are being considered in countries trying to confront their troubled pasts (e.g., Iraq).

Nearly all truth commissions have the aim of creating a collective memory about the past. This ranges from official versions of “who did what to whom” to macrohistorical treatises (e.g., what role did religious organizations play in the maintenance of apartheid in South Africa?). The objective of truth commissions is to get widespread acceptance of a historical narrative, typically under the assumption that battling continually over whether historical injustices actually took place (e.g., Holocaust deniers) is not productive.

Some truth commissions are empowered to grant amnesty to gross human rights violators. The theory is that, with amnesty, perpetrators will come forward and admit their crimes, allowing a collective memory to be constructed. Amnesty schemes are controversial because by definition they create a retributive justice deficit. Amnesty provisions vary widely, from individual to blanket amnesties, and are often accompanied by selective prosecutions of those not qualifying for amnesty (e.g., those who committed their crimes without political motives). Many social scientists believe that amnesties play a valuable role in democratization processes by allowing the forces of the ancien régime to retire from politics and to refrain from acting as “spoilers” of the transition. Others, however, point to the failure to achieve retribution as a crucial flaw in amnesty programs and argue that, without the punishment of wrongdoers, little deterrent to future human rights abuses exists.

Reconciliation is a more complicated concept, in part because some would limit reconciliation to the relationship between victims and perpetrators, whereas others treat the concept as referring to entire societies. The South African Truth and Reconciliation Commission, for instance, was charged with transforming South African society—which, of course, was overwhelmingly comprised of bystanders, not victims and perpetrators of gross human rights violations. Generally, reconciliation requires that people of disparate political views tolerate one another and agree to limit political competition to peaceful and democratic means.

The form that truth commissions take—their structure, functions, and powers—is typically hotly contested by competing political factions, which makes such tribunals hard to establish in the first place. A key issue in such disputes concerns the evenhandedness of the commission’s activities, and in particular whether all sides in political struggles should be held accountable to the same human rights standards. Some distinguish between “victor’s justice” and “transitional justice,” with the latter being characterized by a willingness to cast blame for human rights atrocities broadly across all combatants. With truth commissions crucially situated to shape political transitions on a broad scale, it is no wonder that getting agreement from those formerly at war with each other is difficult, and in many instances impossible.

By almost universal agreement, the most successful truth commission in the world is that of South Africa. Led by the cleric and anti-apartheid activist Desmond Tutu, and fully backed by Nelson Mandela, the first president of the country to be elected after the end of apartheid (but not backed by the governing political party, the African National Congress), South Africa’s TRC adopted societal transformation as one of its most important objectives. Although widely known (and often criticized) for granting amnesties to some of the apartheid regime’s worst assassins and criminals, the TRC held hearings throughout the country involving enormous numbers of citizens, produced a massive documentary history of apartheid and human rights abuses, fought the battle to provide compensation to victims, and generally contributed to tolerance and reconciliation in the country. Consequently, the South African TRC is widely copied by those seeking to move beyond the past toward a more democratic future.

Reconciliation and democracy are not synonymous, but without some degree of reconciliation, it is difficult for countries to put the violent conflicts in the past and agree that political competition will be limited to peaceful and democratic means.

TUBMAN, HARRIET
1822–1913

Born Araminta “Minty” Ross on the plantation of Anthony Thompson, in Dorchester County, Maryland, in 1822, Harriet Tubman was one of nine enslaved children of Harriet “Rit” Green and Benjamin Ross, both slaves. During the mid-1820s, Thompson’s stepson, Edward Brodess, took Rit and the children ten miles away to his own farm in Bucktown after he inherited them from his deceased mother. Over the next twenty-five years, Tubman endured painful separations from her family while being hired out to cruel masters who beat and starved her. Brodess sold several of her sisters, permanently tearing apart her family.

While working as a field hand as a young teen, Tubman was severely wounded by a blow to her head from an iron weight thrown by an angry overseer at another fleeing slave. This left her suffering from headaches and epileptic seizures that affected her for the rest of her life. About 1844 she married a local free black named John Tubman, shedding her childhood name in favor of Harriet.

Upon Brodess’s death in 1849, Tubman determined to take her own liberty rather than risk being sold to settle Brodess’s debts. She tapped into an Underground Railroad network operating on the Eastern Shore of Maryland: Using the North Star and assistance from white and black helpers, she found her way to freedom in Philadelphia. Once safely there, Tubman worked as a domestic to support herself and save enough money to help family and friends escape from the Eastern Shore of Maryland.

Through a variety of familial, social, and abolitionist networks, Tubman was able to exploit secret and reliable communication and support systems and craft her own Underground Railroad networks to freedom. These networks included many free and enslaved African Americans and antislavery whites who lived and worked near crucial access points to food, transportation, and shelter in Maryland, Delaware, Pennsylvania, and New York. Unable to read or write, Tubman also used a variety of disguises and ruses to affect her multiple escape missions. In spite of debilitating seizures, Tubman returned about thirteen times during the 1850s, bringing away roughly seventy friends and family members, while giving instructions to scores more who found their way to freedom independently. Miraculously, Tubman was never betrayed and never “lost a passenger.”

The Fugitive Slave Act of 1850 left many runaway slaves vulnerable to recapture. Tubman brought numerous freedom seekers to safety in St. Catharines, Ontario, Canada, where they became part of a growing community of refugees from slavery. Her dangerous missions won her the biblical name “Moses” and the admiration of abolitionists throughout the North, including Frederick Douglass, William Lloyd Garrison, Lucretia Mott, Gerrit Smith, and Susan B. Anthony, among others, who supported her and sought her counsel. Tubman collaborated with the legendary John Brown as he planned for an attack on Harpers Ferry, West Virginia, in 1859.

During the Civil War (1861–1865), Tubman traveled to Port Royal, South Carolina, to support Union activities. She nursed wounded black soldiers and conducted important spying missions behind Confederate lines. She became the first woman to command an armed military expedition when she guided Colonel James Montgomery and his black troops on a successful raid in June 1863.

After the war, Tubman moved to Auburn, New York, where William Henry Seward, President Abraham Lincoln’s secretary of state, had sold her a home and where she had settled her aged parents and other family members. There, she intensified her fight for women’s rights and civil rights for African Americans. After John Tubman died in Maryland, Harriet Tubman married Nelson Davis, a veteran, in 1869. She struggled financially the rest of her life. Denied her own military pension, she eventually
received a widow’s pension and, later, a Civil War nurse’s pension.

Rising above social, economic, and physical adversity, Tubman continued her humanitarian work with the opening of the Harriet Tubman Home for the Aged in 1908 in Auburn. She continued to appear at local and national suffrage conventions until the early 1900s. She died at the age of ninety-one on March 10, 1913, in Auburn.

Since her death, Tubman has been memorialized and commemorated in many ways, including the naming of schools, roads, nonprofit social-service organizations, and state days of recognition. In 1944 the U.S. Maritime Commission launched the Liberty ship SS Harriet Tubman, and in 1978 and again in 1995 the U.S. Post Office issued postage stamps in her honor. Tubman has earned international acclaim as a symbol of the struggle for freedom, equality, and justice from oppression and discrimination, and has become one of America’s most enduring historical figures.

TULIP MANIA

SEE Great Tulip Mania, The

TULSA RIOT

On the evening of May 31, 1921, a mob of people appeared at the Tulsa County Courthouse in Tulsa, Oklahoma. They were drawn by rumors afoot in the community that Dick Rowland, a nineteen-year-old black man, would be lynched. Those rumors, in turn, were started by a story on the front page of the *Tulsa Tribune* that Rowland had been arrested for attempting to assault an orphaned white girl in an elevator in a building in downtown Tulsa the day before. Rumors of lynching drew black men, veterans of World War I (1914–1918), to the courthouse as well. They hoped to prevent what they feared would be a lynching of Rowland. In the late evening hours, around 10 p.m., the black men who had shown up to prevent the lynching clashed with police and the mob. And the riot began. By the time it ended around noon the next day, thirty-five blocks of the prosperous black section of Tulsa had been burned, leaving thousands homeless and thousands of black people in custody.

Tulsa was the last of the terrible World War I–era riots that began in East Saint Louis, Illinois, in 1917 and continued in Chicago and many other cities in 1919. The Tulsa riot was also likely the worst in terms of loss of life. Like the other riots of the era, Tulsa had its origins in the rising prosperity of the black community, as well as its rising aspirations, which caused the black community to come into conflict with the white community. People in Greenwood, as the black section of Tulsa was known, were doing well; there was a weekly newspaper, churches, rooming houses, schools, stores, even two movie theaters. And many of the Greenwood residents were men who had fought in World War I. They had traveled the world and seen that life might be organized differently from how it was in Tulsa. They returned, as one newspaper said in the riot’s aftermath, “from the war in France with exaggerated notions of social equality and thinking [they could] whip the world” (*Tulsa Tribune* 1921). Thus, people in Greenwood participated in the national renaissance of black culture and pride. They read the vehicles of the renaissance, like W. E. B. Du Bois’s *The Crisis* and the sensational *Chicago Defender*. When they heard that Rowland was in danger, they acted to protect his life. And in doing so they put in motion events that led to the destruction of their own community.

After the riot began, the Tulsa police department acted to put down what was called at the time a “negro uprising.” The police chief deputized hundreds of men and told them to get a gun and “get a nigger.” The police department worked in conjunction with local units of the National Guard to disarm Greenwood residents and take them to what newspapers called “concentration camps” around the city. Those who refused to give up their weapons peacefully were shot. The arrests and fighting continued throughout the night, but around dawn of June 1, the deputies, working in conjunction with a mob and the police and National Guard, swept through Greenwood. First, residents were arrested and disarmed; then looters followed and, once they had taken everything of value, homes and businesses were burned.

In the aftermath of the riot, virtually every African American resident of Tulsa was left homeless. Thousands left the city, never to return. Others vowed to rebuild, even in the face of opposition from the city. The mayor wanted to relocate the black section of Tulsa farther away from the city and to convert the burned area into an industrial and railroad center. “I’ll keep what I have until I get what I lost” was the rallying cry of many in
Greenwood. And, despite receiving little assistance from the city, Greenwood was rebuilt. Meanwhile, an all-white grand jury blamed the riot on African Americans. About the same time as the riot, the Ku Klux Klan was gaining membership throughout the state. Riot victims could not hope for justice through the courts at the time.

The Tulsa riot has received renewed attention due to the Oklahoma legislature’s Tulsa Riot Commission, which in 2001 recommended that the surviving victims receive reparations from the state. In 2003 a team of lawyers led by Harvard Law School Professor Charles Ogletree filed a federal lawsuit on behalf of riot victims, which was dismissed in 2004. The few remaining Tulsa riot victims and their lawyers continue to seek compensation from the state legislature and elsewhere.

TURGOT, JACQUES

1727–1781

Born in 1727 in Paris, economist Anne-Robert-Jacques Turgot, Baron de l’Aulne, received a thorough education, especially in philosophy, and then studied theology at the Sorbonne. In 1750 he was elected to the office of prior. In the same year, he published his Philosophical Review of the Successive Advances of the Human Mind, which contained a four-stage theory of human development. After the death of his father in 1751, Turgot began an administrative career. In the late 1750s he contributed several entries to the Encyclopédie edited by Denis Diderot (1713–1784). His friendship with the Marquis de Gournay (1712–1759), a French economist, merchant, and government official, had a lasting impact on Turgot’s interests and acquainted him with contemporary English political economy. In the late 1750s Turgot met with the head of the physiocratic school, François Quesnay (1694–1774), whose work he admired. He also became friendly with another leading member of that school, Pierre-Samuel du Pont de Nemours (1793–1817), and with Voltaire (1694–1778) and the mathematician and philosopher J. A. N. Caritat de Condorcet (1743–1794).

In 1761 Turgot was appointed intendant of Limoges, a post he held until 1774. He was in charge of the collection of direct taxes, justice, economic and social policy, infrastructure, and so forth. In this period, he composed what may be called his magnum opus, Reflections on the Production and Distribution of Wealth, which was not published until 1769 and 1770 in serial form in the Ephémérides. In addition, he wrote essays on several economic themes, including taxation, public administration, mines and quarries, the grain trade, and the rate of interest. During his visits to Paris he met, among others, David Hume (1711–1776) and Adam Smith (1723–1790).

With Louis XVI’s (1754–1793) succession to the throne in 1774, Turgot was appointed minister of finance. He carried out a number of reforms, including the restoration of domestic free trade of grain, an act that caused the grain riots of early 1775, and the abolition of other constraints on trade (Faccarello 1994). A retrenchment of the influence of the guilds and a replacement of the corvée with a more general land tax followed in January 1776. These measures met with fierce opposition, causing Turgot’s dismissal in May 1776. In 1778 he was elected president of the Académie des Inscriptions et Belles Lettres. He died in Paris in 1781.

Turgot was arguably one of the most important economists of the eighteenth century. In important respects, he developed the physiocratic doctrine and anticipated some of the ideas subsequently elaborated by the English classical economists from Adam Smith to David Ricardo (1772–1823). In the Reflections, he expounded central economic concepts, including the idea that in conditions of free competition the rate of return on capital tends to uniformity across all employments. In his view, self-interest constrained by competitive conditions can be expected to yield desirable economic outcomes. He therefore advocated laissez-faire and is considered a “patron saint” of the French liberal economics tradition of the middle of the nineteenth century (Groenewegen 1977). His writings had an impact on a number of economists, including the Austrian Eugen von Böhm-Bawerk (1851–1914). Joseph A. Schumpeter’s (1883–1950) contention that Turgot...
anticipated in important respects the so-called marginal revolution is, however, difficult to sustain.

TURNER, NAT

C. 1800–1831

Abolitionist and rebel Nat Turner was born circa October 2, 1800, on the Virginia plantation of Benjamin Turner, the child of an enslaved woman named Nancy (the name of Nat's father is unknown). Little is known about either parent. Family tradition holds that Nancy landed in the neighborhood in 1795, the slave of a refugee fleeing the revolt in Saint Domingue. Evidence indicates that after being purchased by Turner, Nancy was used as a domestic servant. Later in life, Nat Turner insisted that his father ran away when he was still a boy.

Early on, blacks and whites alike came to regard Nat as unusually gifted. Upon being given a book, the boy quickly learned how to read, “a source of wonder to all in the neighborhood” (Greenberg 1996, p. 45). As a devout Methodist, Benjamin Turner was not only aware of Nat’s literacy, he even encouraged him to read the Bible, as did his paternal grandmother, Old Bridget, who Nat later said was “very religious, and to whom I was much attached” (p. 44). Even assuming that some of what Nat later told to attorney Thomas R. Gray was exaggerated bravado—or that the white lawyer’s editorial hand helped shape the pamphlet published as *The Confessions of Nat Turner* (Baltimore, 1831)—there is little reason to doubt Nat’s assertion that he spent every possible childhood moment “either in prayer” (p. 45) or in reading books purchased for white children on nearby Southampton County farms and estates.

Aware of his unique abilities, young Nat “wrapped [himself] in mystery” (Greenberg 1996, p. 45). When not doing light work in the fields, Nat kept to himself and “studiously avoided mixing in society” (Greenberg 1996, pp. 44–45). Unlike other enslaved boys, he neither played practical pranks on others nor touched liquor. Told by both his mother and grandmother that he was “intended for some great purpose,” the unusually serious child devoted his limited leisure moments to “fasting and prayer” (Greenberg 1996, pp. 44–45). As was later said of abolitionist Frederick Douglass, whites spoke of Nat as being too clever to be raised in bondage, and Benjamin Turner once remarked that the boy “would never be of service to anyone as a slave” (Greenberg 1996, p. 44).

In 1809, Benjamin Turner’s oldest son Samuel purchased 360 acres two miles away. Nancy, Nat, Old Bridget, and five other slaves were loaned to Samuel to help him establish his cotton plantation, a move that became permanent the following year when Benjamin died during a typhoid epidemic. It may have been at this point that Nat adopted the surname of Turner as a way of linking himself to his ancestral homeland rather than as an act of homage to the deceased Benjamin Turner. Although the evidence for a spouse is circumstantial, the Richmond *Constitutional Whig* later reported that Turner married a young slave woman; this may have been Cherry, who in 1822 was sold to Giles Reese when Samuel died and his estate was liquidated. Turner was sold to Thomas Moore for $400, an indication he was regarded as a prime field hand. Despite being short of stature and a little knock-kneed, Turner’s shoulders were broad and well muscled from more than a decade of hard labor.

Embittered by the forced separation from his wife, Turner turned to fasting and prayer. He avoided large spiritual gatherings on Sundays, but at night in the quarters he willingly described what he had discovered during his solitary readings of the Bible. Sometime in 1825, while working in the fields, Turner had his first vision. “I saw white spirits and black spirits engaged in battle,” he later recalled, “and the sun was darkened—the thunder rolled in the Heavens, and blood flowed in streams” (Greenberg 1996, p. 46). Certain that he was ordained to bring about Judgment Day, Turner began to conduct religious services at Barnes’s Church near the North Carolina border. Most whites scoffed, but at least one man, Etheldred T. Brantley, an alcoholic overseer on a nearby plantation, asked Turner to baptize him before an interracial crowd at Pearson’s Mill Pond.

On May 12, 1828, Turner experienced his most epochal vision to date. “I heard a loud noise in the heavens,” he remembered, “and the Spirit instantly appeared
to me" (Greenberg 1996, p. 46). The voice instructed Turner to take up the “yoke” of Christ, “for the time was fast approaching when the first should be last and the last should be first” (Greenberg 1996, p. 47). Warned not to act until given a further sign by God, Turner was instructed to continue teaching but not to breathe a word of his plans to his family or friends.

Several months later, Thomas Moore died, and Turner became the property of Thomas’s nine-year-old son Putnam. When the boy’s mother remarried to Joseph Travis, a local wheelwright, Turner and the other sixteen slaves on the Moore plantation found themselves under the supervision of yet another new master. When an eclipse of the sun took place in February 1831, Turner concluded that the time was near to act. He recruited four trusted lieutenants, Hark Travis, Nelson Williams, Henry Porter, and Sam Francis. Turner had known Travis for years, as he was also a slave on the Moore plantation and now under the supervision of Joseph Travis. The five initially established July 4 as the date of the uprising, but Turner fell ill, due perhaps to fasting, and the target day passed. Since evidence exists that Turner was merely part of a much larger, two-state revolt, it is also possible that he was waiting for bondmen across the border to rise first.

Turner’s precise goals remain unclear. He may have planned to establish a maroon colony within the Dismal Swamp, or the black evangelical may have preferred to leave the next step in his plan to God’s will. But once the town of Jerusalem was within the grasp of his army, he could either fortify the hamlet and wait for word of the rising to spread across the countryside or retreat into the swamp and establish a guerrilla base in the interior. According to the Norfolk Herald, Turner later confessed that he planned to conquer “the county of Southampton [just] as the white people did in the revolution” (Greenberg 1996, p. 48).

The rebels began around 2:00 A.M. on Monday, August 22. Turner struck the first blow, but failed to kill Joseph Travis with his hatchet. Hark finished the work, while others killed the four other whites in the house, including the Travis baby in its cradle. By noon the slave army had grown to roughly seventy armed and mounted men. They had sacked fifteen houses and killed sixty whites; Turner killed only Margaret Whitehead. As they neared Jerusalem, a column of eighteen volunteers attacked the insurgents. Turner’s men waded into the group, but the tide turned when reinforcements arrived. During the fighting, six of Turner’s men were wounded, and several others, too drunk to continue, abandoned the army and made their way back to the quarters. By Tuesday, only twenty rebels remained. In hopes of bolstering their numbers, Turner rode for the plantation of Dr. Simon Blunt, who owned sixty bondpeople. Understanding that the revolt had failed, Blunt’s slaves cast their lots with the winning side. When they attacked the rebels with clubs and pitchforks, Turner’s army collapsed. Among those badly wounded was Hark Travis, who survived only to be hanged on September 9.

The conventional wisdom that Turner was mentally unstable began immediately following his death on November 11, 1831. Southampton authorities refused to dignify his theology with the term “religion” and instead insisted that his desire to be free was “instigated by the wildest superstition and fanaticism.” At the height of the Jim Crow era, area whites still spoke of seeing Turner’s skull, which was retained as a curiosity. Most described it as abnormal. The publication of William Styron’s Pulitzer Prize–winning fiction, The Confessions of Nat Turner (1994), only contributed to the modern characterization of the slave general as a dangerously irrational rebel. But rural Americans in the antebellum years would have had an equally difficult time understanding the rationalist tone of Styron’s world. During the Jacksonian era, many Americans, white and black, devoutly believed that the end of time was near, and that Christ would soon return to rule his earthly kingdom. To that extent, Turner was well within the popular millenarian religious tradition of the period and was hardly abnormal for his time.

TURNER, VICTOR 1920–1983

One of the most influential and respected anthropologists of the mid- to late twentieth century, Victor Turner made his name as an ethnographer of south-central Africa, and in doing so, became known as a theorist on social structure and process, with particular emphasis on ritual, symbol, and performance. In more than a dozen books and
numerous articles he authored, co-authored, or edited, he concentrated on topics including social drama, social fields, symbolic action, symbolic multivocality (or compression), transition, liminality, communitas, and structure and anti-structure (a term he coined).

Born May 28, 1920, in Glasgow, Scotland, to a stage acting mother and an electronic engineer father, Victor Witter Turner attended Bournemouth Grammar School in England and did undergraduate study in modern and classic literature at University College, London (1938–1941). His studies were interrupted by war, in which, as a conscientious objector, he served as a noncombatant soldier in London. During the war, in 1943, he married Edith Lucy Brocklesby Davis Turner, with whom he would build a lifelong working partnership and parent six children between 1944 and 1963—five to reach adulthood. Drawn to anthropology from about the time of the war's end in 1945, Victor Turner studied in London under Daryll Forde and other leaders in the discipline, proceeding for his doctorate as part of the University of Manchester department coalescing around the South African-born Max Gluckman. This study took him to Africa as a Research Fellow of the Rhodes-Livingstone Institute and back to Manchester, where, upon receiving his doctorate in 1955, he stayed to write and lecture in anthropology for several years.

During this period he dropped and added some important affiliations. Having been active in the Communist Party of Great Britain in youth, he withdrew, disaffected, by his mid-thirties, or by about 1956, when the Soviet military crushed dissidence in Hungary, upsetting pacifists abroad. Between then and 1958, he and Edith joined the Roman Catholic Church in Stockport, near Manchester. In Catholicism they found ritual, and evidently faith, to fill a void left after leaving those to which they had become exposed in Africa. (Some other leading British anthropologists, notably Edward Evans-Pritchard and Godfrey Lienhardt, were similarly drawn to Catholicism after studying African cultures and their religious dimensions.) In their new faith and practice, the Turners also found solace after the death of their afflicted fourth child, Lucy, in her infancy in 1959. Identifying with Catholicism, however, cost Victor Turner the favor of some of his Manchester colleagues.

After a year’s research fellowship at Stanford University (from 1961) and a return to Manchester, the Turners moved to the United States, where Victor wrote more than half of his books and Edith several more. There Victor served consecutively as professor of anthropology at Cornell (from 1964), professor of anthropology and social thought at the University of Chicago (from 1968), and professor of anthropology and religion at the University of Virginia (from 1977 until his death in 1983).

Intellectual influences on Turner were diverse. Most centrally they included his parents (especially his mother, on drama and performance); his wife Edith; Max Gluckman (on social structure and process, and on the ritual expression and resolution of conflict); and Arnold van Gennep (whose work on rites of passage became a keystone for his own on that topic and related ones). He also gained inspiration from anthropologist Clifford Geertz, sociologist Kurt Lewin, psychoanalysts Sigmund Freud and Carl Jung, philosopher Wilhelm Dilthey, and drama scholar Richard Schechner. Not least, Turner gained intellectual guidance from informants and guides in Africa, including individuals he identified as Samutamba, Sakazao, Kajima, Windsor Kashinakaji, Muchona, and Ikelenge—some of whose lives and interactions he wove into his writing.

**RESEARCH IN AFRICA**

Turner’s career was built upon his studies in Northern Rhodesia (later Zambia), which he carried out as a Research Officer of the Rhodes-Livingstone Institute toward the end of the period of British colonial rule. With Edith he conducted ethnographic research by interview, participant-observation, and other means among the Ndembu (part of the larger Lunda population—all classed as Bantu-speaking). This they did from December 1950 to February 1952 and from May 1953 to June 1954, mainly in Mukanza village, Mwinilunga District. About the Ndembu people he wrote, over many years and with much help from Edith, a chain of overlapping, theoretically innovative ethnographies that together comprised one of the most detailed and integrated records then available on any small society living in Africa south of the Sahara.

The roughly 17,000 Ndembu people practiced shifting agriculture, hunting, and gathering in forests and clearings, and some lived in mining and trading towns. Their plateau homeland lies within the so-called matrilineal belt that crosses the southern middle of Africa. Among rural Ndembu, Turner construed matriline (tracing descent through the female line) and virilocality (wives moving to their husbands’ homes upon marriage) as together causing social stresses and strains. He found, for instance, fathers’ loyalties torn between their sisters’ offspring (their own known biological kin) and their wives’ offspring (less surely so). As the Ndembu and others in the Lunda region had been involved in a series of regional conquests and colonizings, including by the British, he supposed Ndembu patterns of kinship and leadership might be in a period of transition.

But it was their immediate lifeways, and especially their rituals, that captured his attention. To Turner they represented social drama, but not just that. Periods of cri-
sis, he saw, brought social and micropolitical tensions into the open, forcing rifts or reconciliations. Typically, he found, the process had four phases: breach, crisis, redressive action, and reintegration. His doctoral thesis, published in 1957 as *Schism and Continuity in an African Society*, built on Gluckman’s work on ritual-political process; but to it he added elements of willful decision making and contingency, including what he came to call purposive “symbolic action.”

Social ills tie into other ills, too, Ndembu people showed the Turners. Divination, healing, and exposure rituals (rituals of affliction) conducted on an ad hoc basis, contrasted with the more predictable, elaborate, and formulaic life-crisis rituals (a kind of rite of passage)—for instance, among Ndembu, the *nkang’a*, a girls’ puberty ritual and celebration of matriliny. Affliction rituals address bodily malfunctions, psychological troubles, and social schisms, or indeed all these at once. Turner argued in *The Drums of Affliction* (1968) that in a society surrounded by dangers and disease—and one that is also disrupted by seemingly arbitrary, indirect colonial rule—rituals provide security, reconciliation, emotional catharsis, and also some sense of transcendence over uncertainty. Rituals have reason, he argued. They serve current needs, not just dead traditions. No ethnographer had analyzed social structure and process with closer attention to emotion.

RITUAL PROCESS AND SYMBOLIC ACTION

Following van Gennep’s broadly comparative work in a more geographically limited but topically holistic way, Turner perceived in rites of passage three stages or subtypes: separation, margin (or limen—a threshold “like a tunnel” of transition), and reaggregation. In his most influential book, *The Ritual Process* (1969)—a collection of essays—he elaborated van Gennep’s concept of liminality: a condition of limbo, of suspension between, sometimes following symbolic death and preceding symbolic rebirth, and sometimes occurring in seclusion or on a journey. He contrasted social structure (a more ordinary condition of hierarchies and dividedness) with what he named anti-structure (a more amorphous condition of flux, equality, and potential growth) that he discerned in liminal conditions. Often in the latter he perceived what he called *communitas*: the temporary condition and feeling of unity, submission, and liberation existing in times and places where usual social barriers were brought down and internal differences of rank and status were erased.

As Turner saw things, symbols work in ways more complex than mere signs. In *The Forest of Symbols* (1967) and other works, he described ritual and religious symbols as “multivocal” or polysemous—that is, as being given many meanings and interpretations. Sometimes they are phased with a single ritual—but they can refer to more than one thing simultaneously, evoking what may not be clearly known or consciously perceived. The color triad of white, red, and black, given prominence in sacred or religious rituals around the world, also, in Turner’s view, carried local, culturally specific meanings, interpretable only in terms of each other and of other local values. For instance, to Ndembu people, the *mudiyi* tree with its white latex, figuring in girls’ puberty rites (*nkang’a*), stood for breast, milk, matriliny, feminine distinctiveness and solidarity, continuity of tribal custom, and unified opposition, among other things. But some of its meanings were activated only in relation to other objects, colors, words, or acts. Symbols crystallize polarities and unify disparate significata (by metaphorically linking different domains of experience). Individuals manipulate symbols and their meanings in rituals. Understanding of how this happens can require insiders’ (both expert and lay) perspectives for “exegetical meaning,” an outsider’s perspective for “operational” meaning (for instance, in terms of social structure), and a broad outlook for “positional” meaning—for instance as part of a system of objects, actions, and understandings.

Turner’s later works led him beyond contemporary Ndembu into world history and into broad public culture. Turner was struck by commonalities between the liminal phases of ritual in small-scale societies and religious pilgrimages, as periods of submission on the way to greater status or power. But he also noted instances of more enduring liminality in monasteries, convents, and communes. In *Dramas, Fields, and Metaphors* (1974), as in *The Ritual Process* before, he likened crisis episodes in the nascent periods of many world religious movements to the transient conditions giving rise to the rock counterculture and antiwar protests in larger movements during the 1960s and early 1970s. In such diverse movements he noted criticism of broader society and its hierarchies and inequities, as well as a potential for willful social change. But whereas in smaller, tribal societies’ initiation rites a liminal phase or condition was obligatory, in larger-scale ones, participation in dramas such as concerts and theater plays—other sites of potential criticism from which change might originate—was more optional, and hence not strictly liminal yet still liminoid. Although he generalized rather more and made bolder leaps of association in his later works than in his earlier ones, it was the books on Ndembu and Africa that remained the focal points of his renown.

SCOPE OF INFLUENCE

Victor Turner defies easy classification. Never was he just an empiricist or a theorist, but always something of both.
As an anthropologist he drew upon a closely focused and fieldwork-intensive British functionalist approach that remained important from about the early 1920s until the 1960s, as well as upon a broadly comparative French structuralist approach influential in the 1960s and 1970s. But he devoted more attention to diachronic process, individual choice, and emotion than either functionalists or structuralists typically did. His work tied French, English, and American schools of thought to African realities, integrating more than compromising. All this moved him from the liminal status of fieldworker to the prominent posts he held in major centers of the anthropological profession. Even when involved in party politics in youth, and in church religion in adulthood, Turner sometimes tested authority and contravened orthodoxy, as if both needing hierarchic structure and wanting a way of release from it. In any case Turner remained a political idealist throughout his career, and something of a spiritualist. He hoped for a more unified and just society, arguing for recognition of the sense and dignity of tropical African lifeways, including their symbolic and religious elements, and tracking the hopeful elements of popular political and religious movements. Turner’s colleagues (who usually called him Vic) and his students generally deemed him nurturing, peaceable, and conciliatory. In these ways he represented to them something like what one of his favorite symbols, the milk of the mudyi tree, represented to Ndembu.

Even social and cultural anthropology’s great breadth of topics could scarcely contain the range of his eclectic interests, from ancient history to experimental drama to brain science (these last two traceable to his parents’ seemingly disparate interests). His musings, late in life, that the complementary functions of the brain’s hemispheres might relate somehow to the symbolic polarization he had long observed in ritual and aesthetic life remained hypothetical, untested, and unsung. Arguably his neuropsychological interest was ahead of his time, but he was hardly alone in his quest to conjoin, or at least reconcile, the arts and the sciences.

Turner’s legacy can be taken as a whole or in parts, and construed as the product of a lifetime, a marriage, or a transcontinental collaboration. While strong waves of critical political-economic scholarship on race, class, gender, and international linkages nearly submerged his early work on micropolitics from the early 1970s on, other aspects of his work proved more buoyant in the shifting currents. He re-explained them while widening his comparisons in his later works, and in those his widow Edith continued editing and publishing after his death in 1983. In his work on ritual process, liminality, communitas, and symbols with multiple meanings, his influence extends far beyond African and Euro-American studies, and beyond anthropology into psychology, sociology, comparative religion, public health, and other fields.

Parker Shipton
TUSKEGEE SYPHILIS STUDY

From 1932 to 1972, the U.S. Public Health Service (USPHS) sponsored an observational study of syphilis in black men in Macon County, Alabama. This trial has come to be known as the Tuskegee syphilis study. Six hundred black men, 399 with syphilis and 201 without, were observed for forty years to chart the effects of untreated syphilis. Perhaps the most famous example of unethical modern medical research in the United States, three features of the Tuskegee syphilis study are instructive: its racism, its perseverance, and its lack of scientific value.

RACISM

The racism of the Tuskegee syphilis study is evident in its design, its justification, and its implications. The misguided popularity of social Darwinism at the turn of the twentieth century is perhaps the most generous explanation available for the views expressed by Joseph Earle Moore (1892–1957), one of the nation’s leading venereologists, and Taliaferro Clark (1867–1948), chief of the USPHS Venereal Disease Division. Previously, Moore had argued for the treatment of syphilis to (1) diminish its effects on the patient and (2) limit its possible spread. In reviewing the design for the Tuskegee syphilis study, he suggested, surprisingly, that it would be a laudable study. Perhaps to mollify any concerns about the racist nature of the design, Moore suggested that syphilis in the black male would be an almost entirely different disease than syphilis in the white male. It is unclear why he made this claim, but even if it were true, it would not diminish the effects on the patient or eliminate the spread of the disease, primarily, of course, to other blacks. In the buildup to the syphilis study, Clark offered a more overtly racist justification for the experiment. He argued that the low intelligence of blacks meant that they would not seek treatment for syphilis. Observing, and not treating, was justified because these men would not choose to be treated anyway.

Offering dubious or overtly racist justifications, the Tuskegee syphilis study condemned these black men and their sexual partners to continual exposure to syphilis and its painful effects. The study also condemned Macon County, a primarily black county, to a robust population of syphilitic men and thereby guaranteed the continued presence and spread of the disease.

PERSEVERANCE

The Tuskegee syphilis study faced a number of obstacles and setbacks that could have easily ended the study. For starters, it was difficult to entice subjects to be tested and, once tested, to return for other exams. Ironically, the researchers successfully enticed subjects to enter the trial by offering them treatment. This, of course, is a surprising turn because (1) treatment was the very thing that the investigators had predicted the black population would not seek, and (2) it was a lie—there was no plan to treat these men for syphilis.

The covert nature of the experiment precluded telling the men that getting treated elsewhere would be detrimental to the study. Accordingly, there was also a constant risk that these men would get treatment through other sources. To eliminate this possibility, the USPHS secured the agreements of local doctors, the Alabama Health Department, and the U.S. Army. Each group agreed to exclude subjects of the study from the antisyphilitic treatments they offered (or, in the case of the Army, required of) others. In the 1950s, penicillin became the standard treatment for syphilis. Though it cannot undo previous complications, penicillin does prevent the disease from producing further complications. By and large, though, subjects failed to procure adequate doses of penicillin during the course of the study.

This study was also under the purview of the Center for Disease Control and could have been cancelled at any given review point. In 1965 the study was reviewed, and the reviewers concluded that it should continue and that the “race issue,” if it were brought up at a later date, could be deflected.

SCIENTIFIC VALUE

The scientific value of the Tuskegee syphilis study was limited by its aim, its execution, and its origin. At the time the study was planned, there already existed some modestly effective treatments for syphilis. This, at the very least, raises serious questions about the value of an observational study. Without any clear benefits for the subjects or the possibility of promising scientific knowledge, the aim of the trial is unclear. That no improvement on existing diagnostic or treatment options was being pursued is further confirmed by the researchers’ response to the introduction of a highly effective treatment for syphilis (penicillin)—they did all they could to keep the subjects from taking it.

During the execution of the trial, control subjects, who started the study without evidence of syphilitic infection, were transferred to the study group if, at a later date, they were positively diagnosed with syphilis. As any student of science can attest, transferring subjects from the control group to the study group is sure to muddy the results.

The origins of the Tuskegee syphilis study are as significant as any other limit on its ultimate scientific value. The planning of the study depended upon a particularly racist version of social Darwinism. Without critiquing this
view, one can still note that the trial continued even after this view was no longer accepted in the scientific community. Designed around a problematic and ultimately untenable perspective, the results of the study lack any scientific or medical value.

A LESSON FOR RESEARCH ETHICS
In courses on medical ethics and research ethics around the country (and perhaps even further), the Tuskegee syphilis study, alongside the Nazi experiments during World War II (1939–1945) and the Willowbrook studies of hepatitis in mentally disabled children from 1956 to 1971, is used as an example of medical research gone wrong. The difference is that the Nazi experiments and the Willowbrook studies both produced useful knowledge (the Nazi experiments produced a wide array of knowledge about the physiological workings and limits of the human body, and the Willowbrook studies correctly identified the distinction and the possibility of inoculation for hepatitis A and B), while the syphilis study produced nothing of value. The Tuskegee syphilis study reminds us that medical research can use ethically impermissible methods to achieve many things, but medical research can also fail to accomplish anything more than an expression of the worst of our social views.

TWIN STUDIES
In the social sciences, the twin study has become an important source of information about the contribution of “nature” to human traits and dispositions. Twin studies are particularly used in clinical and psychological research aimed at attempting to find the genetic component of certain disorders, such as schizophrenia, as well as of intelligence and various personality traits. The British scientist Francis Galton (1822–1911) was the first to suggest that the study of twins might unlock the mysteries of nature. In the 1870s Galton, who sought a methodology that could conclusively show the primacy of hereditary factors in human nature, suggested that the life histories of twins could be used to weigh the relative powers of both nature and nurture. However, Galton cannot be credited with the invention of what is now known as the classical twin study because he merely collected life histories from twin pairs in England through the use of self-report surveys.

The first two classical twin studies, published in 1924, were conducted in Germany and the United States. In the context of understanding the pathologies of races, families, and twins, the German dermatologist Hermann W. Siemens (1891–1969) suggested comparing the correlations (r) of identical or monozygotic (MZ) twins on a given trait to correlations of fraternal or dizygotic (DZ) twins on the same trait. The American psychologist Curtis Merriman (1875–1975), who at this time still needed to convince his readership that two distinct types of twins actually existed, reported correlations of identical and fraternal twins on a number of attributes, with the former showing higher correlations than the latter. Several statistical calculations for estimating the heritability coefficient have been reported, the most basic being 2 (r_{MK} – r_{DK}). This formula provides an estimate of the total variance of a given trait that may be attributed to genetic variance.

Twin studies are used to estimate the heritability of a trait, although the concept of heritability is often misunderstood. It was first described in 1936 by Jay Lush (1896–1982), a professor of animal breeding. Lush distinguished between two types of heritability: broad (H^2) and narrow (h^2). Narrow heritability is of most interest to the social sciences. The heritability coefficient obtained through the classical twin study is an estimate of h^2. Narrow heritability can be understood as the proportion of the variance in a given twin study that can be attributed to genetic variance.

This definition encompasses the following important points. (1) Heritability refers to variance within a population; it does not describe the relative importance of genetic factors at an individual level. (2) Heritability is an estimate of genetic variance in a specific population, at a specific point in time, under specific environmental conditions; these estimates are variable over time, location,
Twin Studies

and population. (3) Estimates of heritability describe the genetic variance within a given population; they are not valid for comparisons between different populations. (4) Environmental conditions may improve the strength of the heritability estimates. (5) Heritability does not necessarily measure the genetic contribution to a trait. Suppose, for example, a researcher is interested in using the classical twin-study method to find a heritability estimate for the condition of having two eyes. The researcher would find that, in most cases, all of their MZ and DZ participants have two eyes, thereby expressing no variance, and resulting in a heritability estimate of zero.

Calculating $b^2$ from classical twin studies rests on an important premise: the equal environment assumption (EEA). Since MZ twins share 100 percent of their genetic material, and DZ twins share on average only 50 percent, one might assume that any observed differences between the two types of twins are due to genetic variance. However, in order to calculate $b^2$ from classical twin studies, researchers must first assume that MZ twins and DZ twins share the same environment, thus allowing researchers to isolate the magnitude of genetic influences on a trait without environmental confounds. Critics of twin studies have long pointed out that MZ twins generally experience similar environments and treatment that are more similar than that experienced by DZ twins, particularly if the DZ twins are of different genders.

In response to such criticism, twin-study proponents reformulated the EEA into the equal trait-relevant environment assumption (trait-relevant EEA), which assumes that MZ and DZ twins have equal exposure to only those environmental influences of known relevance to the trait under study. But critics of the trait-relevant EEA argue that MZ twins spend more time together, are more likely to engage in similar activities, are similarly treated by others, and are more likely to have similar friends than DZ twins. Therefore, since MZ twins experience a more similar environment than DZ twins overall, they are also more likely to have greater exposure to environmental influences that affect a given trait than DZ twins.

In addition to the classical twin study, other methodologies are available for comparing the differences between twins. The co-twin control method is the only twin-study design that attempts to manipulate environmental influences. In this type of study, the genetic component is held constant, and the researcher manipulates the environment. Only MZ twins can be used in such a study. One twin becomes the control participant, while the other is given an environmental intervention. Scores on the trait of interest are measured before and after environmental manipulation. The correlation between the twin pairs before the intervention is measured against the correlation in their scores afterward. The resulting coefficient is a measure of the effects of the environment on the trait under study. This method, however, has largely been discontinued due to its history of misuse, most notably in the twin studies conducted by Nazi doctor Josef Mengele (1911–1979) at the Auschwitz concentration camp during World War II (1939–1945).

Adoption studies are often referred to as twins-reared-apart studies, since one or both of the twins is separated from the biological parents and placed with a relative or an adoptive or foster family. Typically, MZ twins who are reared apart (MZA) are compared to MZ twins reared together (MZT). In adoption studies, correlations of MZAs on a given trait are compared to MZTs. Occasionally, DZ twins reared apart are used as well. In most cases, researchers are interested in establishing trait similarity across a number of different measures. The underlying assumption of adoption studies is that twins have been placed randomly into homes, with minimal or no contact with each other. Although this assumption is almost never accurate, the results from twins-reared-apart studies have been very influential in the social sciences.

The most significant twin-study findings resulted from two large-scale systematic adoption studies: the Minnesota Study of Twins Reared Apart (beginning in 1983) and the Swedish Adoption/Twin Study of Aging (beginning in 1984). These studies reported medium to high correlations between MZAs and MZTs on a number of variables, including IQ, physical traits, and a long list of personality traits. In addition, the Swedish Adoption/Twin Study found moderate to high correlations for processes specifically related to aging, such as memory decline. The conclusion reached in these studies is that genetics are responsible for trait similarity, and that environmental factors have little influence. Critics of these results have pointed to researcher bias, vague or missing data, the denial of access to collected raw data, and the dubious separation of the twins involved in the studies.

Genetics research has at times generated heated ethical and political debates. For example, some authors have commented that studying the genetic components of traits will lead to a resurgence in the eugenics movement and, in particular, the misuse of heritability research on intelligence by some proponents of genetic engineering. Despite these concerns, twin studies and the field of behavioral genetics have had an undeniable impact in the sciences and culture. The progress of this field of research has helped to shift the public discourse on genetic research in favorable directions. With advances in microgenetic research and the continuing development of genomic sciences—particularly as they relate to health promotion and disease prevention—twin studies are likely to become a less-prominent technique for estimating genetic effects than they have been in the past. In any case, because of the
methodological shortcomings of twin studies, the estimates that such studies provide for the heritability of attributes and processes should be analyzed carefully and critically.

TWO-SECTOR MODELS
Broadly speaking, the two-sector model is an analytical framework that embodies stylized dynamic economies with two production processes. Each sector is devoted to the production of a unique good, and there are usually two factors of production that can freely move across sectors. This analytical framework abandons the rather limiting restriction of the one-sector model, in which the same aggregate good is devoted to both consumption and capital. The two-sector framework allows for the study of dynamic effects of economic policies on each sector and the possible interactions between the two sectors. These effects can also be studied in models with several sectors of production, though in these latter models the analysis may not be tractable. Two-sector models are found in many areas of economics. In international economics, the two-sector framework arises naturally in economies with tradable and non-tradable goods. In analyses of economic growth, the distinction is usually between consumption and capital. More recent research has focused on other pairings: physical and human capital, physical production and R&D, home and market goods, and cash and credit goods.

John R. Hicks (1937) introduced a two-sector model for examinations of consumption and investment, as a way to compare the predictions of newly developed Keynesian theories with what he then viewed as the "typical classical theory." In this model, there are two production processes that are represented by two production functions. Each production function contains only one factor, labor, which can be shifted at no cost from one sector to the other. There is a given relative price at which the consumption good can be exchanged for investment. This relative price is determined by the functional forms of the two production functions. The value of output or aggregate production is then the sum of the values of consumption and investment. Similarly, Santi K. Chakrabarti (1979) argues that Keynes's theories should be studied in a two-sector framework and reformulated in terms of wage units.

Hicks's model is concerned with short periods of time, because the quantity of physical capital available in the economy is taken as fixed. James E. Meade (1961) and Hirofumi Uzawa (1963) provide early analyses of the dynamics of two-sector models examining consumption and capital. Another two-sector model is considered by James Tobin (1965). In Tobin's model, one sector produces the physical good, which can be consumed or invested. The other sector is a monetary asset issued by the government to finance public spending. The creation of money affects the capital-labor ratio in the economy. This ratio varies with the rate of inflation. In this second group of models the economy is assumed to save a fixed proportion of income. A further step is taken by Duncan K. Foley and Miguel Sidrauski (1971), who postulate a non-constant saving rate—according to them, the propensity to save may depend on the interest rate and total income. Still, this saving function is ad hoc in that it is not derived as the solution of a behavioral maximization process. The formulation of the optimal amount of savings was posed by Frank P. Ramsey (1928) as a one-sector planning problem. This approach was later extended to two-sector models. Thus, at each moment in time a representative individual may decide on the level of consumption and investment, and the optimal amounts of production in the two sectors.

There are three main types of production functions that have been used to describe the production processes in two-sector models. The first models used von Neumann linear production function in which output is proportional to the amount of labor and capital used. A
second generation of models used Harrod-Domar production functions, where the two factors of production are perfect complements, and therefore the amounts of capital and labor needed to produce a unit of output must be in a fixed proportion. The third type of production function is the neoclassical production function, which drops the assumption of a fixed capital-labor ratio to produce a unit of output and assumes that the same amount of output can be produced with different combinations of the production factors. The neoclassical production function also exhibits constant returns to scale, which implies that if we double the amounts of production factors then output produced is also doubled. This production function has been extensively used in growth theory and many other areas of economics, and it is a centerpiece of current research. However, it has been criticized because of the difficulty of measuring the capital stock. This is known as the Cambridge capital controversy: If the assumption of one single good is abandoned, then aggregate capital cannot be measured independently of the interest rate. There is therefore a circularity in the determination of aggregate capital and the interest rate; moreover, the demand for capital may not be downward sloping.

The early 1990s witnessed a new surge of growth models intended to analyze why some countries are richer than others or why they may grow faster. This new generation of so-called endogenous growth models considers one sector devoted to physical capital and consumption and a second sector devoted to education or human capital accumulation. The available non-leisure time can be spent either to produce physical good or on education. The time spent on education increases the productivity of labor in the future. Therefore, the tradeoff for non-leisure time is between producing physical good today or increasing future labor productivity. The main feature of this model is that it endogenizes technological progress, and hence the growth rate of the economy. Another way to endogenize the growth rate of the economy is to include an R&D sector instead of an educational sector. There are also hybrid models of endogenous and exogenous growth. Endogenous growth may make sense when we consider the world as a whole. However, a small country may take the growth of productivity in the world economy as exogenous, and search for an optimal allocation of production across sectors to increase its total value of output.

Recent research has also analyzed models with heterogeneous agents, external effects from physical and human capital, market frictions, and government interventions. The predictions of these models are generally explored by the time spent on education increases the productivity of labor in the future. Therefore, the tradeoff for non-leisure time is between producing physical good today or increasing future labor productivity. The main feature of this model is that it endogenizes technological progress, and hence the growth rate of the economy. Another way to endogenize the growth rate of the economy is to include an R&D sector instead of an educational sector. There are also hybrid models of endogenous and exogenous growth. Endogenous growth may make sense when we consider the world as a whole. However, a small country may take the growth of productivity in the world economy as exogenous, and search for an optimal allocation of production across sectors to increase its total value of output.

Recent research has also analyzed models with heterogeneous agents, external effects from physical and human capital, market frictions, and government interventions. The predictions of these models are generally explored by both mathematical analysis and scientific computing. The progressive development of numerical methods has allowed researchers to investigate quantitative properties of optimal allocations and effects of economic policies. Several recent studies have been concerned with effects of fiscal variables (i.e., public expenditure, taxes on capital, labor and consumption, and subsidies to education) on economic aggregates such as output growth, consumption, capital accumulation, and worked hours. The two-sector model also appears in several recent papers on monetary theory, exchange rates, and asset pricing.

TWO-STATE SOLUTION

The two-state solution refers to the idea that the most practical solution to the Palestinian-Israeli conflict is one that divides the land historically called Palestine between a Jewish and a Palestinian Arab state. Part or all of the West Bank, the Gaza Strip, and East Jerusalem, which were captured by Israel in the 1967 Six-Day War, would become the Palestinian state. Israel, which has existed since 1948, could see its borders adjusted to fit a new reality. Such an arrangement could effectively end the state of war that has existed between Israel and its Arab neighbors since Israel’s establishment and bring a degree of stability to a region that has suffered four major Arab-Israeli wars, two Palestinian uprisings, cross-border raids and instability, as well as the continuing cycle of violence fed by suicide bombings and targeted assassinations.

HISTORY

The first two-state solution proposal was made in 1937 by the Peel Commission, sent by the British, who then ruled the area, to investigate the motives for Arab unrest. Jewish
immigration from Europe, driven by anti-Semitic violence and seemingly backed by the British, provoked Arab fears of Jewish dominance in historical Palestine, which was overwhelmingly populated by Arabs. The Peel Commission Report claimed that Arab-Jewish coexistence in a single state was impossible because of the unyielding mutual hostility and the conflicting demands for statehood made by the two communities. The report proposed the creation of a Jewish and an Arab state, but the plan was never implemented due to continued Arab rioting.

In 1947 the United Nations voted to partition Palestine into Jewish and Arab states and to internationalize Jerusalem. The Jewish state would comprise 56 percent of Palestine, although Jews only comprised 31 percent of the population, at most, and owned only 20 percent of the land designated for the Jewish state, a fact that caused the Arabs to angrily reject the plan. Zionists, however, argued that many Jews had recently escaped extermination in Europe and had no place to go, and the long history of violent anti-Semitism had demonstrated the need for a Jewish state. The Zionists, therefore, accepted the UN partition plan, if somewhat reluctantly, since they had hoped for more territory.

The 1947 UN partition plan was not fully implemented since no peacekeeping troops enforced the decision. Instead, from 1947 to 1949, war determined the outcome on the ground. In what is called in Israel the War of Independence and by Palestinians the Nakba (Disaster), Zionist forces managed to fight back Palestinian irregulars and military contingents sent by six Arab states to capture more territory than that allotted by the 1947 UN plan. The territory allotted to the Palestinians was taken over by Jordan and Egypt, so no Palestinian state was created. Over half of the Palestinian people fled their homes, creating a massive refugee crisis.

A long stalemate endured until 1967, when Israel captured the remaining parts of historical Palestine from Jordan and Egypt, as well as the Golan Heights from Syria and Sinai from Egypt in the Six-Day War. This war marked a turning point in the history of the two-state solution. Henceforth, the conflict was primarily over the recovery of lands taken in 1967, rather than attempting to reverse the effects of the 1947–1949 war. This turning point became much more apparent in the political arena during the 1980s. The Palestinian leadership gathered in Algiers, Algeria, in November 1988 to both formally recognize Israel and symbolically proclaim a Palestinian state in the West Bank and Gaza, the first time that the two-state solution was officially accepted by the Palestinians.

Since this time, efforts to solve the conflict on the basis of the two-state solution have been undermined by violent extremists on both sides, as well as diplomatic quibbling over the details of an agreement.

The Oslo Accords of 1993 represented another attempt to solve the conflict based on the principle of “land for peace,” the concept that underlies the two-state solution; however, Oslo was an interim agreement and did not explicitly make provisions for a Palestinian state. Nevertheless, it was widely expected that the final status arrangements that were to be concluded by 1998 would result in the establishment of a Palestinian state. Negotiations broke down before the final status agreement could be concluded. In July 2000 Israeli prime minister Ehud Barak and Palestinian president Yasser Arafat (1929–2004) attempted to reach a peace agreement at a summit held at the U.S. presidential retreat in Camp David, Maryland, with the mediation of U.S. president Bill Clinton. Although many far-reaching proposals were considered, the negotiations were ultimately unsuccessful.

LATER DEVELOPMENTS
International efforts to solve the conflict have revolved around the “Road Map,” a plan sponsored by the United States, the United Nations, the European Union, and Russia. According to the plan, if the Palestinians cease violence against Israelis and reform their political system, a Palestinian state will be created with provisional borders, to be adjusted during later negotiations. For their part, the Israelis must stop settlement activity in Palestinian lands. As of 2006, the Road Map had not resulted in a peace agreement. Nevertheless, Prime Minister Ariel Sharon's unilateral “disengagement” from Gaza, in which Israel withdrew its forces from the Gaza Strip and evacuated Israeli settlements there, reinvigorated interest in peace efforts such as the Road Map.

The 1990s saw the rise of a challenge to the two-state solution in the binational (one-state) principle. There is more than one version of the one-state solution, but common to all is the vision of both Palestinians and Israelis sharing the entire land of Palestine as equal citizens, rather than dividing it between them into two states. The binational solution has risen in popularity, particularly among Palestinians and some leftist Israelis due to the increasing difficulties of implementing the two-state solution. Because the growing number of Israeli settlements on Palestinian land, including Arab East Jerusalem, as well as the “separation barrier” that Israel began constructing in 2002, may drastically reduce the territory available for a Palestinian state, proponents argue that the two-state solution is no longer viable and a shared state is preferable. Such a solution would eliminate the Jewish character of the state, since its Jewish majority would soon disappear under Palestinian demographic pressure, a problematic proposition from an Israeli standpoint. The binational solution does not have the significant international or domestic support that the two-state solution currently
enjoys, but it increases in popularity with each failure of the two-state solution.

TYRANNY OF THE MAJORITY

Although the specter of an unwise and unrestrained majority has haunted the democratic imagination since the trial of Socrates (c. 470–399 BCE) in ancient Greece, the concept of majority tyranny dates to the modern age of democratic revolutions. The emergence of large groups of individuals from the “lower” classes of society as political actors in the English civil wars of the seventeenth century prompted philosopher John Locke (1632–1704) to articulate the first conception of majority rule in his Two Treatises of Government (1690). A century later, the revolutionary experiences in America in 1776 and France in 1789 cast the prospect of rule by “the people” in a new, more threatening, light. The phrase “tyranny of the majority,” first coined by French historian and political theorist Alexis de Tocqueville (1805–1859) in his seminal two-volume study Democracy in America (1835–1840) and memorialized by John Stuart Mill (1806–1873) in his classic 1859 treatise On Liberty, represented to this generation the fear and deep distrust of rule by an uneducated democratic mob.

Democracies were thought vulnerable to two distinct forms of majority tyranny. The first is political or legal tyranny that operates through the formal procedures of majoritarian rule. Where all aspects of government, and political theorists, and even some judges, are a function of the majority, its power is absolute. As Tocqueville put it in the first volume of Democracy in America (1835), “politically speaking, the people have a right to do anything” ([1835–1840] 1990, p. 259). This political tyranny was the primary concern of American founder James Madison (1751–1836) in The Federalist Papers (1788), especially No. 10, in which he famously sought to quell anxieties that a majority “fac-

tion” would impose its biddings on an enlightened minority by calling attention to the natural obstacle of the diversity of opinions in a large republic.

The second type is the moral or social tyranny the majority exercises through custom and the power of public opinion. “As long as the majority is still silent,” Tocqueville observed, “discussion is carried on; but as soon as its decision is irrevocably pronounced, everyone is silent.” More insidious than the overt tyranny long practiced by monarchs and despots, which was physically brutal but powerless to inhibit the exercise of thought, under this new form of “democratic despotism,” as Tocqueville would come to call it, “the body is left free, and the soul is enslaved” ([1835–1840] 1990, pp. 263–264).

In On Liberty (1859), his famous defense of individual freedom, Mill deepened Tocqueville’s diagnosis of this second type of tyranny by warning against the “despotism of custom” and “collective mediocrity” endemic to egalitarian societies, while defending expressions of individuality not in harmony with the “tyranny of prevailing opinion and feeling” ([1859] 1982, pp. 136, 131, 63). Yet Mill had reviewed each volume of Democracy in America as they appeared in English translation two decades earlier, and he emended Tocqueville’s account in important ways. While very sympathetic on the whole, in his review of volume two Mill suggested that Tocqueville had overgeneralized by associating all the causes of this new form of majority tyranny with the rise of democracy. Drawing on insights from his own 1836 essay “Civilization,” composed after reviewing Tocqueville’s first volume the year before, Mill argued that the “growing insignificance of individuals in comparison with the mass” was less the result of a transition from aristocracy to democracy than of the progressive growth of wealth and industry he termed “Civilization.” The ills identified by Tocqueville emanated not from an omnipotent democratic majority per se but from an emergent commercial class. “The most serious danger to the future prospects of mankind,” Mill concluded, “is in the unbalanced influence of the commercial spirit” ([1840] 1962, p. 155).

As far as Tocqueville could see, there were no barriers against the absolute sovereignty of the majority. None, at least, that naturally would attend it; “precautions” needed to be actively pursued. Still, despite the omnipresence of majority power, Tocqueville believed the “cautiousness of the people” in the “townships, municipal bodies, and counties” was outside its reach. More specifically, the class of lawyers, rendered “very hostile to the revolution-

Against tyranny of the second type, which was entirely “an affair of the mind,” remedies were more complicated. Here the problem was less one of political procedure than a question of the formation of individual character. Dropping the language both of majority and tyranny, Tocqueville despaired in volume two of *Democracy in America* of not having an appropriate term to describe the new “species of oppression.” In chapter 6 of book 4, he wrote powerfully of “an immense and tutelary power” that “compresses, enervates, extinguishes, and stupefies” rather than tyrannizes, reducing each nation to “nothing better than a flock of timid and industrious animals, of which the government is the shepherd.” The “rare and brief exercise” of free choice offered by periodic elections would not be enough to prevent citizens from gradually losing the faculties of thinking, feeling, and acting for themselves, and thus gradually falling below the level of humanity” ((1835–1840] 1990, pp. 318–321). Sharing this diagnosis, Mill sought, most memorably in *On Liberty*, to remedy the deficiency of “personal impulses and preferences” by fostering an environment of diverse, conflicting opinions where more robust individual characters could grow. In addition, he insisted upon support for a “contrary spirit” to check the dominant commercialism, which he found in the agricultural, leisured, and learned classes of society.

Because they perceived that in the United States the majority did not, as European aristocrats had feared, use their political sovereignty to make laws against the rich, Tocqueville and Mill saw the second kind of tyranny as the far greater threat. Other than the wealthy, they believed, all other political minorities were fluctuating; therefore, “he who is in the majority today is in the minority tomorrow,” ([1835] 1962, p. 205) as Mill put it, though he did point out that the antipathies of race and religion were an exception. The racially divided society of twentieth-century America has given the first type of tyranny of majority a renewed relevance. Legal scholar Lani Guinier (1994) has written eloquently about the problem of permanent and fixed minorities. Though fair in principle, the procedures of winner-take-all majority rule ensure in practice that ethnic or racial minorities will be perpetually powerless. Guinier has outlined a more cooperative style of decision making based on the “principle of taking turns,” which alleviates political tyranny by compelling majorities to confer with minority groups in the hope of generating a more inclusionary politics that is not a zero-sum game.

UNCERTAINTY
In neoclassical theory, markets are portrayed as stable economic systems, with changes in variables having their desired effects: There is a strong tendency for the economic system to converge toward a position of equilibrium. Economic agents are assumed to have all reliable information for decision making, and the future is known with certainty. Any “uncertainty” regarding future events or outcomes is reduced to a probabilistic distribution.

In heterodox economics, and in post-Keynesian theory in particular, however, markets and economic systems are chaotic and unpredictable (Moore 2006). The economic system is set in what is called “historical time”; that is, the past is known and cannot be changed, but the future is unknown and cannot be predicted. This also suggests that we do not simply move from one position of equilibrium to another: The passage of time implies that during the interval when we are shifting, other variables may also be changing, such that a final position of equilibrium is difficult to predict and may never even exist. In other words, the economy is path-dependent: It is continuously moving such that there is no final position of rest.

The source of this instability is the uncertain future and how it affects motives and the decision making of all agents. Indeed, fundamental uncertainty is a central argument of post-Keynesian theory. It is defined as a situation in which agents do not know the future: It is the pure absence of knowledge. This was a central feature in Keynes’s theory of effective demand (see also Knight 1921; Shackle 1967). As Keynes tells us in this memorable passage (1973, p. 113):

We have, as a rule, only the vaguest idea of any but the most direct consequences of our acts…. By “uncertain” knowledge, let me explain, I do not mean merely to distinguish what is known for certain from what is only probable. The game of roulette is not subject, in this sense, to uncertainty…. The sense in which I am using the term is that in which the prospect of a European war is uncertain, or the price of copper and the rate of interest twenty years hence…. About these matters there is no scientific basis on which to form any calculable probability whatever. We simply do not know.

As Keynes makes clear, uncertainty is not the same as risk. In such a situation, outcomes are usually known, or
at least the probability of possible outcomes known with certainty. But let us be clear: Uncertainty is not a situation in which agents cannot compute possible outcomes or probabilities or do not have sufficient information. Gathering more information does not make the future less uncertain.

Uncertainty affects decision making in many ways. For instance, if firms do not know the future or cannot predict future levels of effective demand or growth rates, how can they take a rational decision regarding investment? If central banks cannot know with certainty future levels of inflation or output, how can they correctly take decisions about interest rates? Similarly, how can banks lend to potential borrowers if they do not know whether they will be able to repay their loans, given the uncertain levels of effective demand in the future? The presence of uncertainty also leads to the emergence of power and hierarchical relationships: Faced with uncertainty, agents will try to capture the biggest share of wealth by exerting power over other individuals and social groups (Monvoisin and Rochon 2006).

Despite the pervasive nature of uncertainty, it does not lead to nihilism. Post-Keynesians have developed theories and policies that incorporate uncertainty (see Rochon 2006). Indeed, even when faced with uncertainty, agents, of course, still make decisions. Agents rely on “rules of thumb”: They will rely on past decisions, assume the near future is relatively similar to the present, follow the decisions taken by others, or simply postpone taking a decision.

UNCLE TOM

Uncle Tom is associated with negative, self-denigrating attributes. An Uncle Tom is a black person who is submissive, docile, self-effacing, a race traitor, and psychologically dependent on, nonthreatening to, and always anxious to please, and gain the validation of, whites. Though Uncle Tom is associated with negative qualities, its history is much more complex. Its origin is traced to two major works. The first is the 1849 autobiography of a black slave, Josiah Henson, whose experiences and personality supposedly inspired the second, Harriet Beecher Stowe’s 1852 novel Uncle Tom’s Cabin. Henson was a slave on a plantation in Montgomery, Maryland, owned by Amos Riley. His autobiography catalogued the cruelties of slavery. He escaped to Canada in 1830, settling in Dresden, Ontario, Canada, where he started the Dawn Settlement, which provided opportunities for fugitives to learn skills. He also assisted in establishing the British American Institute, an industrial school for the education of fugitives.

Written in angry response to the Fugitive Slave Act of 1850, which authorized the capture and re-enslavement of fugitives, Stowe’s novel was a scathing indictment of slavery. The central character, Tom, is spiritually and morally superior to his white owners. Tom’s life revealed, in horrific details, the atrocities of slavery. He was repeatedly whipped for refusing his owner’s order to whip fellow slaves. He was sold several times, his last owner beating him to death for refusing to divulge the whereabouts of two fugitive slaves. Even as he lay dying, Tom prayed for, and forgave, his owner.

Stowe came from a white New England abolitionist family and lived in Cincinnati, Ohio, in the 1830s, across the bridge from slaveholding Kentucky. She taught at a school for former slave children and witnessed the atrocities of slavery. Returning to New England in 1850, she decided to write a book detailing her thoughts about slavery. Her depiction of Tom and of other black characters in the book as people who confronted degradation with submission became the source of the concept of Uncle Tom. Tom’s humility, Christian character, and forgiving nature led to the modern association of his name with attributes of compromise and self-denigration.

The paradox of Uncle Tom, however, is that neither of the two characters with which the concept is associated

Uncle Tom
embodied such negative qualities. Stowe’s Tom resisted, albeit in a passive way. He disobeyed orders he deemed inhumane and refused to betray fellow slaves even at the risk of punishment and death. He once risked his life to save a drowning little white girl. Henson’s life reflected similar heroism and nobility. Riley was so incompetent that Henson was left in charge of the operations of the farms. Threatened with seizure by creditors, Riley entrusted Henson with transferring his slaves to Kentucky for safekeeping. For Henson, personal freedom was not an end. He worked hard to help others not only become free but also acquire the skills to make freedom meaningful. These qualities of courage and nobility conflict with the use of Uncle Tom as an epithet for blacks who betrayed their own race or who are deemed submissive and deferential to whites. During the civil rights movement, Malcolm X frequently referred to Martin Luther King Jr. and other civil rights leaders as Uncle Toms. Black officials who oppose affirmative action or race-based policies are tagged Uncle Toms. In 2002 the American Directory of Certified Uncle Toms was published. It ranked over fifty black leaders according to a five-star Uncle Tom rating. Uncle Tom thus became a means of cultural policing to determine who is authentically black.

There are two modern versions of Uncle Tom. The first is the docile, loyal, contented person who accommodates lowly status. The second is the ambitious black person who seems willing to be subordinate to whites in order to achieve a more favorable status. Both characters overtly identify with whites either because of fear or opportunism. It is important, however, to distinguish between Uncle Tom the character and Uncle Tom the concept. Neither the historical (Henson), nor literary (Tom) Uncle Tom was a betrayer or compromiser. Their lives demonstrated courage, rebellion, and nobility. They both resisted. Henson escaped and created the institutions that helped other fugitives adjust to life in freedom. Tom disobeyed orders he deemed inhumane and sacrificed his life rather than betray fellow slaves. Critics have nevertheless mistaken their peaceful strategies and nobility for meekness and compromise. Hence, while the concept Uncle Tom might be negative, depicting a coward and compromiser, the characters from whom it originated did not fit into such negative constructions. Furthermore, the “Tom” epithet is not necessarily a negation of the person’s blackness. It disparages behavioral and idiosyncratic dispositions that contradict perceived collective interests of blacks.

**UNDERACHIEVERS**

In general underachievement is defined as a discrepancy between potential (what a student ought to be able to do) and actual performance (what a student is demonstrating). However, there is little consensus about how best to define underachievement, particularly among gifted students. In some instances an underachieving gifted student is defined broadly, in others cases it is defined as limited to specific criteria. One definition of the underachieving gifted student, for example, is when a gap exists between a student’s achievement test scores or academic grades and intelligence test scores. Such a broad delineation would result in a comparatively large number of students identified as gifted. In contrast, a more specific definition of the underachieving gifted student is one who has a Stanford-Binet (IQ test) score of 132 or above and a percentile ranking of 75 or below on the California Test of Basic Skill. This definition limits the underachieving gifted student to only a handful of students.

Professionals whose responsibility it is to identify underachieving gifted students (UGS) for intervention must keep in mind that whatever definition is decided upon will determine the instruments and types of selection procedures used. The definitions, instruments, and selection procedures will ultimately determine who receives special education programs and who does not.
IDENTIFICATION PROCESS
Typical methods of identifying UGSs rely on standardized measures (for example, IQ tests, achievement tests), teacher perceptions (for example, checklists, grades, assessment of motivation, assessment of daily work, comparisons with other students), and self-perceptions (for example, personal information and insight, comparisons with peers). The most common method of identifying UGSs in the early twenty-first century involve examining the difference between achievement test scores and intelligence test scores. According to the psychologist Anne Anastasi (1976), the statistical nature of achievement and intelligence tests “assures” a percentage of underachievers. Anastasi claims that categorizing students by comparing achievement scores with intelligence scores is a misuse of the test results, since no two tests correlate perfectly (Dowdall and Colangelo 1982). The psychometrician Robert L. Thorndike (1963) further discounted the use of intelligence tests for identifying gifted students, warning that IQ scores should not be used to assume a particular level of performance (Dowdall and Colangelo 1982).

Another method of identifying UGSs is teacher observations. A teacher’s judgments and grades have the advantage of being based upon direct experience with the student. The disadvantage of these measures is that they are often biased. The discrepancy between potential and classroom achievement as measured by teacher assessments often reflects nonachievement factors, such as neatness, good behavior, motivation, and teacher attitudes, rather than pure academic ability. Research has consistently found that teachers tend to rate students who are most similar to themselves in social, racial, and economic background as more desirable and successful compared to students who are dissimilar to the teachers. Another problem with the identification process is an indiscriminate use of the tests to identify the “prototypical gifted student.” This practice is based on the assumption that gifted students are a homogeneous group, all of whom can profit equally from a common curriculum.

Some scholars point out that a more beneficial approach may be to use the information gleaned from achievement and intelligence tests to diagnostically determine the strengths and needs of the individual student, regardless to how the student is classified. With individualized information, curricular modules and activities could be developed that address the particular strengths and weaknesses of each student.

GIFTED UNDERACHIEVERS’ TRAITS
Overall the literature consistently reports positive qualities of interpersonal effectiveness, independence, and self-assurance for academically gifted students and the reverse for UGSs. UGSs appear to have more in common with underachieving average students than with gifted students. Both UGSs and underachieving average students tend to be male and exhibit more social immaturity, more antisocial behavior, and lower self-esteem than gifted students. In addition UGSs and underachieving average students are also more likely to come from unstable, lower income, single-parented homes. The only consistent difference between UGSs and underachieving average students is the high scores of UGSs on standardized IQ and achievement tests.

UNDERACHIEVEMENT CAUSES
A variety of factors contribute to the underachievement of high ability students, including emotional and social problems, lack of an appropriate curriculum, and learning and self-regulation difficulties. The attitudes of teachers and counselors toward a child may also be responsible for the gap occurring between student potential and performance.

Other researchers contend that the underachieving gifted problems are deeply rooted in family interaction patterns or attitudes toward education. Educational psychologists have suggested that underachievement for gifted students is a choice, a form of social self-defense because of strong cultural or peer identification. This phenomenon of “deliberate underachievement” has been found to be particularly evident among gifted adolescent females, as a response to perceived sex-role expectations, and among African American gifted students involved in the process of adolescent impression management, as an attempt to control the perceptions other people form of them.

Other scholars contend that for UGSs it is not an issue involving attitudes so much as one of skills (more precisely, the lack of such) or creativity. Given the wide variety of factors contributing to underachievement in high ability students, it is understandable the students thus affected may demonstrate unique learning needs.

INTERVENTION APPROACHES
Published research on intervention with UGSs can be grouped into two conventional areas. The first group focuses on intensive counseling to address problems of low self-image and feelings of inferiority, while the second group focuses on manipulating the classroom environment.

An overview of the counseling intervention with UGSs indicates that such procedures have not been shown to be consistent or effective. A 1979 study that did report limited success concluded that intensive counseling can be effective only when: (a) counselors are specifically selected and trained, (b) a small number of students are treated, (c) objectives are clearly delineated, and (d) methodology is carefully developed.
Research on the second type of intervention—focusing on altering or modifying the classroom environment—also reported limited success. Critics of these interventions point out that generally such interventions have not begun until high school, although the most crucial time to intervene is during the elementary years. Critics also state that while classroom sizes and ability grouping have been manipulated, teaching strategies, expectations, and curriculum content have not been altered.

Programs that have taken an individualized holistic approach have reported promising results. One such intervention, Joseph Renzulli’s Enrichment Triad Model, is an active process in which students choose to learn. In order to facilitate students becoming creative producers, this model capitalizes on the student’s potential by using an interest-based curriculum, bringing together the student’s ability, interest, learning styles, and a supportive student-teacher relationship.

Given that professionals cannot agree on a definition or the antecedents of underachievement, the adoption of one common intervention is unrealistic. Effective interventions are those that are designed to address the uniqueness of the UGS student in a holistic fashion.

UNDERCLASS
The term underclass was used by Charles Murray in 1984 to describe a permanent or persistent poverty population whose lower-income status passes from one generation to the next because of intrinsically dysfunctional behaviors. This social class is described by Ken Auletta (1982) as a group, largely concentrated in urban areas, that is cut off from society, marginalized, and lacks the skills needed in order to find jobs in the modern economy. William Julius Wilson (1985) defines the underclass as those who lack training or skills, are out of the labor force or long-term unemployed, and who engage in deviant behavior. Wilson also incorporates in his definition family instability and welfare dependency. Erol Ricketts and Isabel Sawhill (1988) produce an empirically operational definition of an underclass area where a census tract has rates of high school dropouts, male labor-force nonattachment, welfare recipiency, and female-headship one standard deviation above the mean for the country as a whole. A person who lives in such a census tract and who engages in socially deviant behavior is considered by Ricketts and Sawhill to be in the underclass.

These definitions of the underclass share many of the features of earlier conceptualizations of populations at the lowest rungs of the social and economic ladder. Karl Marx described the lumpenproletariat as “the lowest sediment of the relative surplus population,” an unproductive and regressive portion of the population unable or unwilling to work (Darity et al. 1994, p. 16). The underclass, in this sense, is “the continuously deprived fraction of the working class … comprised of the persons most frequently relegated to the ‘disposable reserve army,’ often found without work even during times of accelerated capitalist accumulation” (Darity 1982, p. 135).

Ken Auletta, referring to a 1980 report by the Manpower Development Research Corporation, writes that:

These people have been excluded from the regular labor market and find, at most, sporadic employment. Though relatively few in number, they have become a considerable burden to themselves and the public—as long-term recipients of welfare, and as the source of much violent crime and drug addition…. There is nothing new about such a social class. There have always been pirates, beggars, vagrants, paupers, illiterates, street criminals and helplessly, sometimes hopelessly, damaged individuals. (Auletta 1982, p. 25)

A key element of the underclass definition is the superfluous nature of the population and its status as permanently unemployed, underemployed, or unemployable (Myrdal 1963, 1970). The underclass, in this sense, is the stagnant portion of the relative surplus population (Darity 1982, p. 135). Darity writes, furthermore, that in the managerial society the underclass is more comprehensively viewed as superfluous by the dominant social class.
Underclass

than is the case under capitalism. The surplus population serves a function under capitalism; it serves no function in managerial society (Darity, 1990, pp. 248–249).

CAUSES

Two broad sets of causal factors have been offered to explain the existence, size, and growth of the underclass. One set of factors involves behavioral and attitudinal deficits. These include decisions to bear children out of wedlock; participation in illegitimate activities—often destructive, violent activities; and inability or unwillingness to work or obtain the necessary skills in order to become productive members of the labor force. Another set of causal factors offered to explain the underclass are termed structural factors. These include residential segregation that produces concentrations of poverty and pathology, deindustrialization, and the shift of jobs from the inner city to the suburbs (Wilson 1987; Darity et al. 1994). Both the structural and behavioral explanations predict pathological behaviors.

For Murray (1984), the responsibility for criminal involvement, children born out of wedlock, joblessness, and dependency on welfare rests upon the shoulders of members of the underclass themselves. The underclass reproduces its behavior from one generation to the next, just as it perpetually reproduces itself, through excessive unwanted births to teenage mothers and unemployed or unemployable fathers.

For Wilson (1987), the underlying causes are more broadly found in the larger context of structural transformations in the economy. Joblessness in the inner city arises in part from the flight of low-skilled and semiskilled jobs from their historic location in central cities. Social isolation and concentration of poverty are but consequences of these structural transformations. Other structural factors suggested in the literature include sentencing reforms during the 1980s and the rising use of imprisonment as a vehicle for reducing labor surpluses (Darity et al. 1994; Myers and Sabol 1987).

SIZE OF THE UNDERCLASS

One view is that the size of the underclass in the United States is relatively small. The underclass population, in this view, ranged from less than one million in 1970 to somewhere between 2.5 and 3.5 million in 1990. By 2000, using the Ricketts-Sawhill empirically driven definition of underclass, Paul Jargowsky and Sawhill estimate that only about 2.2 million persons lived in underclass areas. They write:

The underclass areas are disproportionately minority, and concentrated primarily in large urban areas, especially in the mid-Atlantic and Midwest areas of the country.... The underclass grew dramatically in the 1970s, edged up further in the 1980s and declined sharply in the 1990s (although not to its 1970 level.) The immediate reasons for the decline were reductions in the number of census tracts with high levels of dropping out of high school and high levels of public assistance receipt. (Jargowsky and Sawhill 2006)

The sharp drop in the relatively small numbers of underclass persons is attributed to welfare reforms during the 1990s that resulted in significant declines in welfare rolls and to inner-city education reforms that helped to fuel graduation rates.

Charles Murray (1999) disputes these conclusions. He feels that the underclass grew during the 1990s. Murray tracks data on persons under correctional supervision, labor-force dropouts, and illegitimacy ratios. There were 1.8 million persons under correctional supervision in 1980 in the United States. By 1997 this number had risen to 5.7 million. In 1985, 5.2 percent of black adults were under correctional supervision. By the end of 1996, there were 9 percent of black adults under correctional supervision. Murray points to statistics showing an increase in the share of black males who are labor-force dropouts and the share of all black births that are illegitimate to underscore his claim that the underclass continued to grow throughout the 1990s. For example, he reports that in 1982, 58 percent of black children were born out of wedlock. In 1997, 69 percent of black children were born out of wedlock. Murray's earlier concept of underclass as arising from poverty and the perverse incentives associated with welfare is later replaced with the concept of intergenerationally and genetically determined transmittal of poverty status. (Herrnstein and Murray, 1994). Murray's change in conceptualization of underclass helps him reconcile how the black underclass could grow even during a period of welfare retrenchment.

RACE AND THE UNDERCLASS

Inextricably intertwined with the definition of the underclass is race. Using 1980 U.S. census data, Ricketts and Sawhill (1988) calculate that 59 percent of persons in underclass areas were black. Ricketts and Mincy (1990) compute that this share dropped from 77 percent in 1970. Murray's definition of underclass points to the disproportionate share of blacks who meet the criteria selected for inclusion.

Even though pains are often taken to clarify that not all underclass areas are black or even poor, it is generally understood that underclass areas are disproportionately poor and black. Indeed, the term black underclass is often used synonymously with the term underclass. This is so
because blacks are disproportionately found among each of the key definitional components of the underclass: concentrations of poverty and labor-force withdrawal; high rates of criminality; and high rates of female-family headship.

Race is highly correlated with place. Low social capital and deviant behavior can be thought of as a manifestation of place or a concentration of pathology in particular neighborhoods. Location in particular neighborhoods, though, could be traced to redlining, mortgage discrimination, and other housing barriers that can be seen as manifestations of race (Wilson 1987; Stoll 2005; Massey and Denton 1993; Jargowsky 1997).

HOW THE UNDERCLASS HAS SHAPED PUBLIC POLICY

Much of the debate about the causes and consequences of the growth of the underclass surrounds the impacts of culture, or shared values, attitudes, and beliefs on the perpetuation of poverty and dependency on welfare. This debate is reminiscent of the culture-of-poverty debates, wherein the behaviors and attitudes of the poor themselves cause their poverty. This notion that the intergenerational transmission of poverty rests in the culture of poverty populations has direct implications for what to do about poverty.

Writing on behalf of the Committee for Research on the Underclass of the Social Science Research Council, Michael Katz summarizes how the term underclass evolved into a metaphor for discussions about inner-city crises and the attendant policy responses. The destructive violence, the threats to law-abiding citizens, and the substantial social costs associated with teenage pregnancies and dependency on welfare invoke the image of a group, mostly blacks, permanently stuck in concentrations of poverty in inner-city areas. The eruption of riots, the dependency on drugs, the distance from conventional morals, and the apparent inability of this population to lift itself out of poverty evoke concerns about policy responses and the social transformations that accompany these changes. According to Katz, “the underclass is a metaphor of social transformation. It asserts the emergence of a new social grouping within America’s inner cities” (1993, p. 22). The term underclass itself evokes images of the undeserving poor, those whose behaviors contribute to their own distress. And, thus, the underclass designation signals a significant turn toward policies designed to eliminate the incentives to reproduce undesirable behaviors.

Policy prescriptions that presume that underlying behaviors respond to incentives and disincentives—the core of the microeconomic-behavioral model of the underclass—suggest that welfare restrictions and increased deterrence through law enforcement and imprisonment will reduce the size of the underclass population. Policy prescriptions that presume that the underlying problems rest in structural transformation require greater reliance on the matching of jobs and residences, reductions in housing segregation, and the breakup of concentrations of low-income and public housing in affected areas. But, both the aforementioned behavioral and structural explanations assume that the underclass is not functionally necessary. An alternative view is that the underclass is permanent in part because of its centrality in maintaining the managerial society (Darity et al. 1994).

Underconsumption

Samuel L. Myers Jr.

UNDERCONSUMPTION

Underconsumption is a macroeconomic phenomenon of deficient aggregate demand resulting from the failure of consumption expenditure to keep pace with rising output. It might equally be described as oversaving. Most (but not all) theorists of underconsumption explain it by reference to a parallel failure of real wages to keep pace with rising labor productivity, so that the wage share in national income tends to decline. Because non-wage-earners save much of their income—unlike wage-earners, who spend all (or nearly all) of their incomes on consumer goods—the ratio of consumption expenditure to total income also declines.

This “low-wage” version of underconsumption theory can be traced back to J. C. L. Simonde de Sismondi and Robert Owen in the 1820s; the slightly earlier theories of Robert Malthus and the Earl of Lauderdale are rather different. It is generally agreed that low-wage underconsumption formed part of Karl Marx’s complex and poorly articulated theory of capitalist crisis. The doctrine certainly reappeared in the writings of his followers, from Karl Kautsky and Rosa Luxemburg before 1914 through to the theory of “monopoly capital” developed by Paul Baran and Paul Sweezy in the 1960s. A slightly different version of underconsumption theory was energetically propagated in the 1920s by the American writers William T. Foster and Waddill Catchings.

In the Marxist tradition underconsumption is seen as a fundamental contradiction of capitalism and a root cause of the Great Depression. It can be overcome only when capitalism itself is transcended through socialist revolution. Many Marxists, however, remain skeptical about underconsumption and emphasize other causes of economic crises, especially capital-intensive technological change that reduces the rate of profit but also (in certain circumstances) militant labor pressure on the profit share.

There is a reformist variant of underconsumption theory, associated with J. A. Hobson, in which it is argued that underconsumption can be avoided through comprehensive measures of social reform. Beginning in the 1890s, New Liberals and social democrats advocated redistribution of income through the tax system, labor market regulation to raise real wages, and the development of a comprehensive welfare state. Hobson and his coauthor Alfred Mummery (1889) had already argued that underconsumption was the principal cause of trade depression, which seriously damaged the interests of the workers, and supported a range of measures to increase real wages (including emigration, trade unionism, and a statutory eight-hour day). Subsequently Hobson argued that the consequences of failure to reform the system might be severe. He believed that capitalist imperialism was very largely a response to underconsumption: Colonial territories offered market opportunities that were unavailable at home because of the restricted purchasing power of the mass of the population. Hobson’s ideas had a profound influence on Lenin and other Marxist theorists of imperialism.

Underconsumption has always been rejected by orthodox macroeconomists on the grounds that the economy has powerful adjustment mechanisms that remove any tendency toward chronic demand deficiency. Say’s Law was originally formulated, by Jean-Baptiste Say himself and by James Mill, largely in response to early advocates of underconsumption, and the law formed the analytical core of pre-Keynesian macroeconomics. Any tendency toward underconsumption, or oversaving, would in this view be eliminated through the inevitable reduction in the rate of interest that would occur; this would induce people to save less and thus to consume more. In equilibrium, output and employment are constrained by supply considerations and not by aggregate demand.

John Maynard Keynes denied that such a self-correcting mechanism could be relied upon because saving depends on income rather than on the interest rate and total output is normally constrained by demand. Not surprisingly, therefore, Keynes had considerable sympathy with underconsumptionist ideas, though he emphasized deficient investment rather than excessive saving and was therefore inclined to believe that increased investment expenditure could (at least in principle) generate enough effective demand to maintain full employment. The Keynesian growth theorists Roy Harrod and Evsey Domar denied this possibility because the capital stock cannot profitably be continually increased relative to consump-
tion expenditure. This criticism is implied by the accelerator principle, which links investment to the growth of consumption; thus, the accelerator is closely linked to underconsumptionist ideas.

Another important heterodox economist with links to underconsumption theory was Michal Kalecki, who famously identified “the tragedy of investment.” Investment adds both to aggregate demand and to productive capacity, but in a capitalist economy, where there is no planning or coordination of investment decisions, it is only by accident that investment spending will be in exactly the correct proportion to consumption expenditure. Kalecki’s version of underconsumption has affinities with both the Marxist and the Keynesian schools.

The revival of pre-Keynesian macroeconomics since 1970, however, has restored belief in Say’s Law and pushed underconsumptionist ideas back into the theoretical undergrowth. Today mainstream macroeconomists regard underconsumption as a faintly ludicrous radical heresy.

UNDERDEVELOPMENT

The theory of “underdevelopment” became popular during the 1970s within development studies, an important subfield within the social sciences. It addresses the question of why economic growth has been elusive in post-colonial countries. Is it primarily because of internal factors, such as local culture, religion, lack of skills, lack of institutions, corruption, and patrimonial relations? Or is it primarily the result of external factors, particularly the power relations within a world capitalist system dominated by a core of industrialized countries exploiting a periphery of poor countries in a form of “neocolonialism”?

Before the 1970s it was common within the modernization school of thought, which arose out of Western Keynesian and neoclassical economic thinking, to regard colonial and postcolonial countries as being “undeveloped.” In this perspective, internal factors were emphasized, and these countries were encouraged to follow particular stages of economic growth in order to catch up and “develop” in a manner similar to that of the Western industrialized countries. The more postcolonial countries integrated within the world capitalist system, it was argued, the more they would reap the benefits through increased aid, trade, and investment.

In contrast, a school of thought emerged which argued that the colonized world was actively underdeveloped by its contact with imperial powers. According to the underdevelopment perspective, which has close links to the dependency and world-systems perspectives, the economies of colonized countries were distorted to meet the needs of emerging capitalism in Western Europe. This was particularly so during the phase of industrialization, when capitalist firms in competition with each other needed cheap labor, raw materials, and new markets for their products. The colonial and postcolonial regions became satellites (or peripheries) of the industrialized countries that formed the metropoles (or centers) of a world system of capitalist expansion, through relations of economic dependency.

The theory of underdevelopment arose within Marxism but as a departure from the classical Marxist view that capitalism, while it exploits and destroys, also develops. As Karl Marx (1818–1883) said in Capital (Vol. 1): “The country that is more developed industrially only shows, to the less developed, the image of its own future” (1954, p. 19). The Russian-born American economist Paul A. Baran (1910–1964) wrote in 1957 that, on the contrary, postcolonial societies were blocked from development by the peculiar manner in which they came into contact with industrialized countries. For Baran, the origins of underdevelopment can be traced back to the plunder and enforced trade of the seventeenth and eighteenth centuries. This was a time, he argued, when Western European colonization of the rest of the world began on behalf of merchant capitalists, to be later followed by producer capitalism. Imperialism, as famously stated by V. I. Lenin (1870–1924), is the “highest stage of capitalism,” as it grows out of the inevitable tendency toward the creation of monopolies. Competition among capitalist firms eventually results in the more successful firms destroying or swallowing the less successful.

Baran argued, however, that monopoly capitalism faced a crisis of overproduction due to the lack of effective demand in the capitalists’ home countries. The economic surplus generated had to be productively absorbed by the
capitalism system if a crisis was to be avoided. Parts of this surplus were absorbed through military expansion, state expenditure (for example, building a welfare state to prevent the working class at home from revolting), and technological innovation. However, this was not sufficient to absorb the massive surplus and create the conditions for the continued accumulation of capital, which is the motor force of capitalism (i.e., accumulation for the sake of accumulation). Capitalism had to conquer new markets and create new investment opportunities, argued Baran, and this could only be achieved through expansion into new territories in the form of colonialism (political and economic dominance) and neocolonialism (economic dominance over politically “independent” countries).

According to Baran, the class interests that came to dominate within these countries, foreign and local, benefited from this state of dependency in various ways. These beneficiaries included domestic landowners, merchants and monopoly capitalists, and the foreign capitalists—none of whom had any real interest in the development of a domestic market that would generate a developmental dynamic within the satellites. Foreign capital in particular was mainly interested in primary resource extraction, where profits are repatriated to the metropoles. This resulted in the development of modern enclaves to serve a very small domestic market composed of expatriates and domestic elites, who aspire to mimic the consumption patterns of the metropolis. The rest of the periphery was composed of an expanding “reserve army of cheap labor” living in poverty in the countryside and in urban slums.

The theory of cumulative causation developed by the Swedish economist and sociologist Gunnar Myrdal (1898–1987) also arose during the 1950s and covered similar ground but from a non-Marxist perspective. Myrdal (1957) laid emphasis on the cumulative development path of industrial countries that had made breakthroughs in science, technology, and industrial production. These countries had large domestic markets with a high demand for goods and services, thus attracting capital into their economies. Poor countries, on the other hand, fell into a downward spiral of stagnation and impoverishment due to, among other things, low savings, small domestic markets, and the low skills and poor health of the work force. Low tax revenue meant that the governments of poor countries could not invest in social and economic infrastructure, except in small export enclaves that benefit foreign capital. These conditions lead to rising intranational as well as international inequality, thus perpetuating the underdevelopment of the periphery.

While Baran favored Soviet style state planning to overcome underdevelopment, Myrdal saw the solution in state-led industrialization and market regulation, where infant industries are protected from foreign competition. These ideas were popularized and refined by a number of neo-Marxist thinkers, such as Andre Gunder Frank (1967), Samir Amin (1970), and Walter Rodney (1971), who argued that the development of Europe rested on the underdevelopment of Africa. This perspective found a ready audience among revolutionary nationalist leaders in the postcolonial world who were not necessarily Marxists. To mitigate the negative impact of neocolonialism and dependency, many countries used the postcolonial state as an active agent of development, with policies ranging from import substitution to a relative delinking from the world capitalist system in the pursuit of self-reliant development.

These strategies during the 1960s and 1970s did achieve some success in growing a domestic market, achieving respectable growth rates, and improving health and education services in many African, Latin American, and Asian countries. However, these achievements were also accompanied by an overreliance on increasingly authoritarian, corrupt, and unaccountable states, and massive borrowing that resulted in an unsustainable debt crisis beginning in the 1980s. This, and the declining fortunes of Soviet state socialism, helped pave the way for the ideology of “free market” neoliberalism to penetrate the periphery.

This period saw the resurgence of modernization theory, albeit couched in the language of “globalization.” During the 1990s, development studies seemed to be in crisis, as globalization theory, whether from the Right or the Left, posited that a “global village” of open economies was being created. National boundaries, it was argued, were being eroded; the state was being replaced by “the market” (i.e., private firms) as a key agent of development, and there was no longer an industrialized core in the “first world” and an impoverished periphery in a “third world.” Instead, global inequality was becoming “detrimentalized” as investment and jobs flowed increasingly to the periphery, leading to increased economic growth and employment, while the industrialized countries experienced greater unemployment and inequality. The only exception is much of sub-Saharan Africa, which remained marginalized from the process of global integration.

The 1997 East Asian economic crisis and subsequent crises elsewhere in the world exposed the vulnerability of the newly industrializing economies, forcing a retreat from neoliberal policies, and the reemergence of the state as a critical actor in development. Writers such as Samir Amin insist that the core-periphery model remains valid. Only two countries, namely South Korea and Taiwan, have risen out of their periphery status, largely because of the privileges they received as U.S. allies during the cold war. For the rest, including fast-developing China and India, rapid industrial growth has followed the pattern of
enclave development. These countries are still reservoirs of cheap labor and seas of extreme poverty. On the other hand, the industrialized "triad" of the United States and Canada, the European Union, and Japan continues to dominate the world economy at the core, with the United States performing the hegemonic role with the help of the World Trade Organization, the International Monetary Fund, and the World Bank. These institutions impose rules on underdeveloped countries that undermine efforts at domestic development, in the interests of transnational corporations that remain firmly based in industrialized countries.

There is now increased recognition that both internal and external factors are responsible for the inability of poor countries to rise out of their conditions of underdevelopment. Poor countries are challenged to democratize internally, develop local capacities, and spread the benefits of economic growth to all citizens. At the same time, they need to act in concert with other countries and civil society organizations to reap the benefits of globalization. Some emphasize regulating capitalism at a global level through transformed global institutions that are reoriented toward the needs of poor countries. Others urge a focus on strategic delinking, especially from the financial markets dominated by the financial institutions of the triad, in pursuit of a "polycentric negotiated globalization" that is governed by democracy, disarmament, and a new system of international law that respects national and regional autonomies.

UNDEREATING

Undereating is a relative term. It refers to a negative energy imbalance that results when energy intake is less than energy that is expended. This negative energy imbalance can occur as a consequence of social conditions (e.g., poverty), medical conditions (e.g., cystic fibrosis), or psychological conditions (e.g., depression). It can also occur during any developmental period, such as in failure-to-thrive infants and in the elderly, who can suffer fat loss as part of normal aging processes. In these instances, undereating is considered to be involuntary because it is attributable to impecuniousness, nutrient malabsorption, or loss of appetite. Undereating, however, can also be intentional, as in self-starvation. Most notably, intentional undereating is pathognomonic in the eating disorder anorexia nervosa.

Anorexia nervosa is characterized by refusal to maintain at least 85 percent of normal body weight for one's age, height, and gender; fear of weight gain; disturbance in body perception; and self-worth based on body weight and shape. These core symptoms cause the individual to relentlessly pursue caloric restriction through behaviors such as dieting, fasting, excessive exercise, and vomiting. Anorexia can also include purging after binge-eating. It is often comorbid with other psychopathology such as depression and substance abuse. Other adverse medical consequences of undereating include emaciation, anemia, tooth decay, hair loss, bone loss, heart and kidney failure, and even death.

As of 2007, the lifetime prevalence rate of anorexia nervosa is estimated to be approximately 1 percent. It is most prevalent in adolescents and young adults who are white, female, and of mid-to-upper socioeconomic status. It is, however, increasingly being diagnosed at younger ages, in males, across U.S. ethnic minorities, and at all levels of socioeconomic status. The research, though limited, suggests that self-starvation is more prevalent in Western countries but that it is on the rise in non-Western countries.

The apparent general increase in prevalence of anorexia across groups and cultures likely reflects the strong influence of regnant sociocultural values. With globalization, the Western media exert a powerful and pervasive influence, conveying explicit and implicit messages that uphold the thin body as the ideal to which many females feel they should aspire. Although sociocultural explanations of anorexia are compelling, studies show that a predisposition to anorexia may be genetically based. Psychological factors such as early trauma (e.g., abuse), a major negative life event (e.g., parental divorce), or a critical transition (e.g., college) may then precipitate disease onset in individuals who are susceptible. It has been suggested that, although maladaptive, the ability to
tightly control one's caloric intake may serve to restore an individual’s sense of power over his or her life.

Anorexia is viewed as both a medical and psychological condition and is notoriously intractable to treatment, with relapse common. A multidisciplinary approach is recommended. When patients are very underweight, hospital or day-program treatment is required, consisting of psychological counseling, nutritional education, and a supervised diet of from 2,000 to 4,000 calories per day. Cognitive-behavioral therapy and family-systems therapy appear to be the most widely used psychotherapeutic approaches. Research is needed, however, to identify the approach that is most effective. Psychopharmacotherapy to treat anorexia has so far met with little success, but research is ongoing in this regard.

UNDEREMPLOYMENT

The labor force concept of underemployment can be defined as a comprehensive way to identify and measure the underutilization of labor resources. In this sense, it goes beyond plain unemployment—being jobless while looking for work—to further include different forms of inadequate employment, such as being discouraged or subemployed, or employed involuntarily in part-time and low-income jobs with marginal or unstable labor market attachments.

The globalization of the world economy and the corresponding industrial restructuring of developed countries—away from manufacturing and towards services—have had a considerable impact on the composition and characteristics of the labor market. While labor force participation has increased, it has also resulted in an important rise in employment hardship with the emergence, among a considerable portion of the labor force, of unstable, poorly paid, and often involuntarily part-time jobs. This new situation has led labor-market researchers to point out the need for a new term (beyond unemployment) to better capture all meaningful forms of employment hardship.

Interestingly, the origin of this researchers’ concern can be traced back to the 1930s in the work of British economist Joan Robinson (1903–1983). At that time, she wisely argued that in a society where no regular system of unemployment benefits exists and where poor households are unlikely to be supported by social institutions (i.e., a social welfare system), individuals who are out of work and who cannot find a job fitting their skills will naturally employ their time as usefully as they possibly can.

Thus, except under peculiar conditions, a decline in effective labor demand which reduces the amount of employment offered in the general run of industries will not lead to unemployment in the sense of complete idleness, but this surplus of labor will rather get employment into a number of occupations still open to them … [where] their productivity is less than in the occupations that they have left. (Robinson 1936, p. 226)

Robinson referred to this phenomenon as disguised unemployment. Other researchers later drew attention to the existence of such disguised unemployment in certain economic sectors (e.g., agriculture), particularly in the economies of developing countries (Moore 1953; Lewis 1954) where the presence of an unlimited supply of labor makes its marginal productivity negligible, zero, or even negative.

Sponsored by the International Labor Organization, labor statisticians have gathered on numerous occasions to discuss and develop concrete measures of underemployment. In this ongoing discussion, American sociologist Philip Hauser (1909–1994) made an important contribution by developing what became widely known as the labor utilization framework (LUF) to capture a more accurate picture of employment, acknowledging both the official forms of unemployment, as well as different categories of economically inadequate employment based on hours (involuntarily part-time work) and wages (poverty-level pay) (Hauser 1974). The LUF has evolved through time and now has both a substantial literature and a more elaborate set of subcategories (Clogg 1979; Sullivan 1978) to better capture the employment situation and to adapt more efficiently to datasets other than the U.S. Current Population Survey (CPS, compiled monthly by the U.S. Census Bureau for the Bureau of Labor Statistics), where all the original empirical work came from.
Nevertheless, the operational definitions of states of underemployment typically used by researchers can be summarized as follows, from the most to the least severe:

Subunemployed is a proxy for “discouraged workers” and includes individuals who are not currently working and who did not look for work during the previous four weeks because they felt no jobs were available.

Unemployed follows the official definition and includes those not working but who (1) have looked for work during the previous four weeks, or (2) are currently on layoff.

Underemployed by low hours (or involuntary part-time employment) parallels the official definition of those who are working “part-time for economic reasons” and includes those who are working less than thirty-five hours per week because they cannot find full-time employment.

Underemployed by low income (or working poor) includes those whose labor market earnings during the previous year, adjusted for weeks and hours worked, were less than 125 percent of the official poverty threshold for an individual living alone.

Underemployed by occupational mismatch (or overeducated) includes those whose educational level (measured as years of schooling) is greater than one standard deviation above the mean education for workers with the same occupation.

All other workers are defined as adequately employed, while those who are not working and do not want to be working are defined as not in the labor force.

Of course, no standardized measure of any important concept will be perfect, and underemployment is not without flaws. Some of these deficiencies are related to problems with the operationalization itself (e.g., using poverty thresholds that ignore cost-of-living differences), while others have to do with other related forms of employment hardship, such as job security, which are not included in the definition. Notwithstanding, these criticisms are minor since underemployment provides a useful way to analyze trends over time, as well as inequality between groups in the prevalence of employment hardship.

In all years, these trends are unequivocally countercyclical, a phenomenon reflected in the fact that underemployment rose and then fell over the 1990s owing to the recession early in the decade and subsequent economic expansion. Inequality between groups in the risk of underemployment is often striking and should be an issue of great policy concern. Women, minorities, the young, and those with low educational attainment are all especially vulnerable to underemployment. Moreover, these vulnerabilities are often particularly acute among residents of rural areas and central cities. As a result, economists continue research (both theoretical and empirical) on the topic to further contribute to the understanding of these trends in employment hardship over time and between groups.

UNDEREMPLOYMENT RATE

Underemployment generally refers to one of several situations that result in employment in an economically inadequate position. In this context the underemployment rate refers to the fraction of those employed who are “underemployed.” Some scholars utilize an alternative version of this definition by considering some nonemployed individuals as underemployed. Regardless of the definition of underemployment, the concept evolved from inadequacies in the unemployment rate in capturing work-related hardships (Jensen and Slack 2003, p. 25).

Ignoring for now the definition of underemployment that includes nonemployed individuals, the underemployed work while incurring some form of employment-related hardship. This includes individuals working in occupations with an insufficient number of hours, individuals working in positions with insufficient pay, individuals working in occupations below their levels of educational attainment, and individuals working in positions involving some combination of the above scenarios. Because they have employment they are not considered to

INTERNATIONAL ENCYCLOPEDIA OF THE SOCIAL SCIENCES, 2ND EDITION

493
be unemployed according to the standard definition of unemployment.

First, underemployment refers to a situation where employees work fewer hours than they desire. Such an event may occur because of real-world labor-market rigidities such as a fixed-hour workweek. For example, workers desiring a thirty-hour workweek at a job that requires forty hours for full-time employees or twenty hours for part-time employees will be considered underemployed if they accept the part-time position. A similar case occurs when workers accept part-time employment without choice, often referred to as “involuntary part-time.” This is the most widely cited reference to the underemployment rate, perhaps because it is easier to measure than the other types of underemployment. John Ham (1982) estimates that in the United States in 1970 over a quarter of the labor force was either unemployed or underemployed according to the hours worked measurement of underemployment.

Alternatively, workers may accept positions that offer the desired workweek but with low pay. In this case workers will be considered underemployed when their expected wages—based on personal (i.e., educational attainment, experience) and job-specific characteristics—are higher than their actual wages. This type of underemployment may occur within the context of either full-time or part-time employment. In a sense, workers accept such employment rather than become unemployed. Measuring the underemployment rate by this definition is difficult due to the need for an empirical estimation of one’s expected wage.

Some scholars consider all working-poor individuals to be underemployed, thereby eliminating the need for wage estimates. Such scholars would likely categorize a full-time employee earning the minimum wage as underemployed. Other researchers note that this need not be the case if the earnings of low-wage individuals are consistent with their level of human capital. Among those who consider all working poor as underemployed, a debate exists as to what the threshold level of income should be. Frequently a percentage of the official poverty threshold (either 100% or 125%) or a fraction of the median wage (from one-third to two-thirds) is utilized. Critics contend that such levels are arbitrarily determined.

Moreover, some workers are in occupations with an adequate workweek and pay but are not using all of their human capital, most notably by not fully using their educational qualifications. For example, individuals with a bachelor’s degree working in positions requiring only a high-school diploma are considered underemployed when compared to degree holders with higher-level jobs. As noted by Stephen Rubb (2005), the same individuals are considered “overeducated” when compared to others in their own occupational category. Measuring the underemployment rate by this definition is difficult due to the need for an estimation of the required level of education (and other human capital characteristics) for various occupations. Implicit in such a calculation of an “occupational mismatch” is the idea that all jobs within an occupational category are homogenous and that educational quality is uniform. Many scholars find such assumptions objectionable. Due to such complexities, researchers tend to focus on underemployment from other categories. A similar concept is “disguised unemployment” introduced by Joan Robinson (1937, p. 84) “where workers’ productivity is less than in the occupation they have left,” presumably because the worker’s new occupation does not make full use of their human capital.

It should be noted that many scholars (e.g., Jensen and Slack 2003) use underemployment to capture all forms of employment hardship, including those associated with nonemployment. As such, their definition of underemployment includes both discouraged and unemployed workers in addition to those employed in inadequate situations. For such scholars, the underemployment rate is the fraction of the labor force that is “underemployed” with a slight adjustment to include “discouraged workers” as part of the labor force. Discouraged workers are individuals who are neither employed nor looking for work, and typically they are not counted as part of the labor force. Using such a definition, Jensen and Slack find that in the United States in 2000 the overall underemployment rate was 13.5 percent, and that it was notably higher during the global recession in the early 1990s. In their model the most common type of underemployment is the working poor. This is followed by unemployment, insufficient hours, and discouraged workers as the second, third, and least common types of underemployment. They do not estimate the level of occupational mismatch in their calculation of the underemployment rate. Researchers who include nonemployed workers in their estimates of the underemployment rate tend to also automatically include working-poor individuals in their calculation. In general, their work tends to focus on issues involving the equitable distribution of income. Other researchers disagree with the inclusion of discouraged and unemployed workers in the estimates of the underemployment rate, contending that underemployment implicitly infers employment.

Underrepresentation

Underrepresentation occurs when members of discernible groups are not consistently present in representative bodies and among measures of well-being in numbers roughly proportionate to their numbers within the population. These underrepresented groups are discernable based on a shared history and an ongoing legacy of disenfranchisement, usually marked by gender, race, ethnicity, class, sexuality, and religion. Underrepresentation in basic social and economic measures, such as adequate housing, income, education, and physical health, generally coincides with a history of disregard, deprivation, and even violence. Access to these basic social goods is necessary to pursue a dignified life and is a prerequisite for the enjoyment of the political liberties of democratic citizenship. When access to these goods coincides with markers of social and political marginalization or exclusion, the exercise of political rights and obligations and the opportunity to achieve a good life, however defined, is severely compromised.

The dimensions of underrepresentation in any society coincide with the access to and exercise of power. Historically, those with power use their influence to define full membership in the polity to include themselves and similar subjects while excluding those they designate as different. This “difference” is not without judgment but is defined as inferior to the privileged groups and as corrosive to the community. In some instances, groups want to assert their social difference but seek to change how a community values it. This is often the case with ethnicity, where an ethnic group wishes to maintain its cultural way of life but demands fair recognition and accommodation of its existence from the state and other members of the polity. However, in other instances members of disadvanta
ged social groups regard their “group” status as illegitimate altogether and strive to dismantle its very meaning and any associated punishments. The goal in this regard is elimination of their status as a “group.” Some consider gender to be an appropriate example of this perspective.

Fair political representation in democratic societies is essential because it is a key democratic activity geared toward generating legitimacy, setting agendas, and establishing the practices and policies under which people live. When identifiable groups of citizens are not present in representative bodies in adequate numbers over time, their interests and concerns tend to be absent, and thus a state of underrepresentation exists. A situation in which women and racial, ethnic, religious, and sexual minorities are overrepresented on the lowest ends of most measures of social and political well-being, while remaining underrepresented on the higher measures, raises the specter of structural inequality. Structural inequality occurs when measures of a good life and indicators of deprivation are visibly and measurably stratified along these lines.

One of the most potent ways to address structural inequality is through political participation and representative government. Yet women and minorities are politically underrepresented across the globe—both in terms of their presence in representative bodies and the interests those bodies address. Some scholars argue that to create more inclusive representative bodies, democratic societies should adopt a semiproportional electoral system that utilizes cumulative voting (Guinier 1994). Others advocate proportional representation through the single transferable vote (as in Ireland and Malta), party-list quotas for women and minorities (Phillips 1995), reserved seats in legislatures for marginalized groups (as in India and Tanzania), and public funding for minorities to organize and select their own slates of candidates (Christiano 1996).

Is it fair to consider an individual’s race, class, gender, or sexuality when deciding on the allocation of scarce goods or opportunities? Is it fair not to? If it is fair, then how should social difference be considered, and what weight should it be accorded? Who decides? If societies maintain that the distribution of goods should be solely based on merit, then how should they determine what is “meritorious” achievement; how should they address what is sure to be an increase in the existing inequality between, for example, whites and nonwhites, men and women, and the economically privileged and the struggling; and who should make these determinations?

If social difference cannot be ignored without serious deleterious consequences but according it too much weight, or too little, is associated with even more negative outcomes than not considering it at all, then the stakes are very high for arriving at any conclusion. At the same time,
answering these complex questions regarding difference and disagreement is a matter of democratic judgment. That judgment cannot be truly democratic or just, however, unless all relevant members of the polity are fully included at all stages of deliberation and decision making.

Experiments with policies aimed at achieving a greater presence of members of historically marginalized groups in representative bodies show promise in India on local councils and in Scandinavian countries on national legislatures. In the United States, experiments at local and state levels, as well as within the national party structures, have produced policies, expanded agendas, and altered the very terms of the debate, which likely would have otherwise remained unchanged. How to go about increasing the presence of marginalized groups, however, is a highly complex endeavor fraught with potential, but very real, dangers.

Hannah Pitkin writes, “We show a government to be representative not by demonstrating its control over its subjects but just the reverse, by demonstrating that its subjects have control over what it does” (1967, p. 232). But this statement begs the questions of who or what is to be represented, and under what conditions representation can be understood as democratic, or even just? All political representation is about the representation of some group; to some degree, whatever proxy is used for the interests (be it geography, party, identity, or some other indicator), one runs the risk of subverting intragroup disagreement and even cementing differences. It is not enough to argue that a particular approach to representation holds the capacity to freeze differences because, to varying degrees, they all do. Any system in which a part stands for the (often heterogeneous) whole is assured to get it wrong on occasion. The challenge is for the part to represent the whole as faithfully and justly as can be made possible through fair and inclusive procedures and processes.

UNEMPLOYABLE

A person is said to be unemployable if he or she is unsuitable for any job. More precisely, someone is unemployable if there exists an absolute mismatch between his or her personal characteristics or attributes (including, for example, education, skills, experience, or physical fitness) and those currently demanded by employers. Unemployable persons are either chronically unemployed or else do not participate in the labor force at all.

Three important features of the contemporary view of unemployability can be associated with the definition given above. First, as is obvious from the definition, being unemployable is identified with the inability to secure any employment. Second, it is commonplace to focus on acquired characteristics (that are amenable to change) rather than innate characteristics (that are taken as given) when accounting for an individual’s status as unemployable. Third, following from the previous point, unemployability is viewed as a state that can and should be remedied by means of appropriate policy interventions. Unemployability has not always been viewed in this way, however. Historically, it has been associated with the ability to gain some employment, but for material reward that is insufficient to support an “adequate” standard of living. Moreover, there has, in the past, been a greater emphasis on innate rather than acquired characteristics when explaining the state of unemployable persons. This, in turn, encouraged a view of the unemployable as morally repugnant persons who needed to be dissociated from the “mainstream” labor force. These sentiments are evident to some degree even in the writings of radical or reform-minded critics of capitalism, such as Karl Marx, William Beveridge, and Beatrice and Sydney Webb.

Because unemployable persons are defined as lacking the attributes desired by employers—and in particular, the sort of human capital firms require—the inevitable tendency is to focus on individual choice and behavior as the ultimate cause of unemployability. However, it is possible that events beyond an individual’s control induce personal characteristics that make the individual unemployable. For example, the family environment and/or schooling that contribute to early childhood development may be responsible for making some individuals unemployable. Alternatively, chronic unemployment may cause skills to atrophy or even come to be regarded by employers as, in and of itself, a negative credential. This can result in an unemployed person eventually becoming unemployable. In this case, rather than unemployability resulting in chronic unemployment, it is chronic unemployment that causes a person to become unemployable—a process anticipated by Beveridge that is now associated with modern views of hysteresis in the labor market. Finally, the mismatch between individual attributes and employers’
requirements characteristic of unemployability may not arise because of any literal deficiency of individual attributes at all. Consider, for example, the effects of the geography of deindustrialization coupled with the relative geographical immobility of labor. It is possible for the skill set in which a geographically concentrated group of workers has invested to be rendered redundant by the decline or relocation of a regionally concentrated industry. This leaves workers with the wrong skills rather than no skills—too few for some remaining jobs, but too many for others—and thus suffering the absolute mismatch between individual attributes and employers’ requirements that renders them unsuitable for any job (at least within a regional context).

Whatever its causes, unemployability can be associated with a variety of social problems. Most obviously, since most individuals depend on the labor market for most of their income, unemployable persons may suffer severe material hardship. Since work also lends meaning and definition to the lives of most people, isolation from work caused by unemployability can lead to dissociative, antisocial behaviors such as violence and crime. It is not surprising, then, that numerous policy measures have been proposed to address the problem of unemployability. Some of these—such as welfare (or workfare) programs and earnings subsidies—are essentially permanent income maintenance schemes designed to offset the condition of unemployability. Other policies, however, seek to remedy the condition itself. For example, the strong association between unemployability and human capital deficiencies means that training schemes are a prominent feature of policy proposals to reduce the number of unemployable persons. If, however, former workers are made unemployable by geographically concentrated structural change as described earlier, broader regional development policies that focus not only on changing individual attributes (through retraining, for example) but also on the level and variety of economic activity in a region may have a role to play in redressing the problem of unemployability.

UNEMPLOYED, HARD CORE

SEE Hard-core Unemployed.

UNEMPLOYMENT

A person is unemployed when he or she is willing and able to work given the prevailing terms and conditions of employment but does not currently have a job. Depending on its causes, unemployment can pose severe problems for both individuals and societies alike. For example, since most households derive most of their income from participation in the paid labor market, unemployment can be a source of considerable material hardship and distress. Furthermore, unemployment can challenge the sense of identity and self-worth that individuals derive from their jobs. Finally, unemployment represents, in the aggregate, a waste of productive resources: society as a whole would be better off if the unemployed were engaged in productive activity.

MEASUREMENT OF AND VARIATIONS IN UNEMPLOYMENT

Because of its importance, economists have long had an interest in the accurate measurement of unemployment. But unemployment statistics are subject to several measurement problems. For example, official statistics usually measure unemployment by requiring that a person’s willingness to work be demonstrated by evidence that they are actively searching for a job. Some economists, however, identify discouraged workers—those who are willing and able to work, but have ceased to search for work because they do not believe that jobs are available—as being unemployed. Despite this, discouraged workers are not included in official measures of unemployment because they are not actively looking for work. They are instead categorized (along with full-time students, retirees, and others) as not participating in the labor force.

Another measurement problem is associated with disguised unemployment. This was originally identified as a condition afflicting developing countries, wherein individuals might engage in very low-productivity work in the agricultural sector for want of a job that would more fully utilize their productive potential. But some economists
Unemployment

now identify involuntary part-time or temporary work—that is, part-time or temporary work performed by those who would prefer a full-time, year-round job—as a form of disguised unemployment. Once again, disguised unemployment is not reflected in official measures of unemployment. This is because all those who have jobs are automatically categorized as employed, regardless of whether or not the jobs they perform fully utilize their productive potentials or satisfy their preferences with respect to the number of hours of paid work they perform.

Whatever their potential flaws, official unemployment statistics reveal a number of important stylized facts about unemployment. First, it has long been established that unemployment varies over the course of the business cycle, rising when the economy enters a recession and falling during a boom. Second, a more recently established stylized fact is that unemployment varies over time between lengthy “episodes” of higher or lower unemployment. For example, average annual unemployment rates in the major industrialized economies were much lower during the 1950–1973 period than they were during the preceding interwar period (1918–1939) or than they have been since 1973. Third, unemployment rates differ across countries at any particular point in time and during the episodes of high or low unemployment referred to above. Prior to 1973, for instance, it was commonly observed that unemployment in the United States was higher than that in Europe. Since the 1980s, however, the United States has tended to experience unemployment below the average rates witnessed in Europe. Finally, unemployment rates differ by age, sex, and race. Unemployment is typically highest among the young (ages sixteen to twenty-five) and members of racial or ethnic minorities. Older workers and women also frequently experience more unemployment than prime-age males, although since the 1970s, unemployment rates for women have become comparable to those for men in some of the major industrialized economies.

EXPLANATIONS FOR UNEMPLOYMENT

What factors cause unemployment and so explain the stylized facts described above? According to some economists, the labor market operates like any commodity market, with variations in the level of wages serving to “clear” the market—that is, equate the supply of and demand for labor. But even when the labor market clears in this fashion, unemployment will exist. This frictional unemployment is often associated with the normal workings of the labor market. It arises because even if the number of jobs available is exactly sufficient for the number of job seekers at currently prevailing wages, the process of matching employers with employees takes time. It is therefore possible for some workers to be without jobs at any point in time. The amount of frictional unemployment is affected by a variety of factors, including the choices of workers themselves. For example, a currently unemployed person might decline to accept an offer of employment in anticipation of a superior subsequent offer. Unemployment that is the product of individual choice in this fashion is termed voluntary.

Other economists, however, claim that labor market clearing is a special case, sometimes called full employment (although not all economists who use the term full employment would agree that it is best conceptualized in terms of labor market clearing). These economists claim that observed unemployment is largely involuntary. According to the conventional definition, involuntary unemployment occurs when the labor market does not clear but is instead characterized by a surfeit of job seekers relative to the number of jobs available at currently prevailing wages. In this situation of “too many workers chasing too few jobs,” the unemployed are without work not by virtue of individual choice but as a result of a constraint that exists on their ability to sell labor. Some economists locate the source of this constraint on the supply side of the economy. For example, there may be impediments to the workings of the price mechanism that prevent wages from varying in the manner required to equate the demand for and supply of labor. Or alternatively, the stock of capital accumulated by firms may be insufficient to warrant the employment of all those willing to work, given the number of workers that need to be combined with a single unit of capital to produce a unit of output.

Other economists, however, locate the source of involuntary unemployment on the demand side of the economy. They argue that the demand for labor (and hence the quantity of employment offered by firms) is derived from the quantity of goods that firms can profitably produce and sell, so that the aggregate demand for goods is the ultimate determinant of employment and unemployment. According to this view, even when wages are free to vary and output can be produced by different combinations of capital and labor inputs (so that the existing stock of capital does not determine the level of employment that can be achieved), it is possible for an insufficient aggregate demand for goods to give rise to an insufficient derived demand for labor relative to the number of persons who wish to work at currently prevailing wages. This is the theory of employment and unemployment originally developed by John Maynard Keynes (1883–1946). Its most important feature is that it identifies as the source of involuntary unemployment a deficient demand for goods, rather than any problems with the functioning of the aggregate labor market that might prevent the latter from clearing.
The distinction between supply-side and demand-side theories of involuntary unemployment leads to a further distinction between classical and Keynesian unemployment. Classical unemployment—which includes frictional unemployment and supply-side involuntary unemployment—is determined on the supply side of the economy and is unresponsive to variations in aggregate demand. Classical unemployment is often associated with the concept of a natural rate of unemployment or a nonaccelerating inflation rate of unemployment (NAIRU). Keynesian unemployment, meanwhile, is determined on the demand side of the economy and does respond to variations in aggregate demand.

It is possible in principle for voluntary and involuntary or classical and Keynesian unemployment to exist within the same economy. However, economists disagree as to what extent observed unemployment is voluntary, involuntary, classical, or Keynesian, and hence on the extent to which these categories, and the theories of unemployment associated with them, are useful for explaining the stylized facts outlined earlier.

**POLICY IMPLICATIONS**

The policy implications of unemployment depend greatly on the theorized causes of unemployment. For example, if unemployment is a product of individual choice (i.e., a voluntary condition), it would not appear that any form of policy intervention is merited. Even if unemployment is entirely frictional, however, it may be prudent to use public policy to reduce unemployment—including voluntary unemployment—by improving the process whereby employers and employees are matched. In this case, supply-side, microeconomic policies designed to affect the choices or attributes of job seekers are appropriate. Unemployment insurance programs might be altered to influence the propensity of those searching for work to accept job offers, or training programs might be established in an effort to imbue the unemployed with the sorts of skills required by currently vacant jobs. If unemployment is involuntary and Keynesian, however, an altogether different approach to policy intervention is required. In this case, macroeconomic policies (such as a reduction in interest rates or an increase in government spending) are needed to raise aggregate demand in order to remedy the deficient demand for goods and hence the deficient derived demand for labor that is the ultimate cause of unemployment. As with the theories of unemployment from which these policy interventions derive, the appropriate policy response to unemployment is—and will likely remain—a subject of controversy among economists.

**UNEMPLOYMENT RATE**

There are two dimensions of the unemployment rate that sit uneasily with each other. First, national statisticians produce the “official” unemployment rate that policy makers, lobby groups, and media commentators use to summarize the state of the labor market. Second, economists attempt to explain the unemployment rate using
microeconomic and macroeconomic models, which do not correspond directly with the statisticians’ framework. The various explanations of unemployment remain highly contested.

DEFINING AND CALCULATING THE UNEMPLOYMENT RATE

Prior to the Great Depression, limited efforts were made to collect labor market data. For example, the gainful worker framework in the United States used the ten-year census to enumerate employment activities with little attention being paid to unemployment. A worker was defined as “a person who works for money” (Smuts 1960, p. 71).

The mass unemployment in the 1930s created a demand for a broader enumeration system, and the modern concept of the labor force framework emerged after World War II (1939–1945) in response. This framework is made operational through the International Labour Organization (ILO) and the conference of International Labour Statisticians. These conferences develop procedures (definitions) for generating national labor force data (see http://laborsta.ilo.org/ for sources and methods). National statistical agencies implement these definitions in periodic sample surveys (usually monthly) and publish labor force estimates. The application of these definitions varies from country to country.

Figure 1 sketches the labor force framework. The labor force concept has two components: (a) criteria defining activity—specifically, willingness and search; and (b) a time period for assessing activity. The working-age population (persons above fifteen years, although some countries exclude those above sixty-five years) dichotomizes into active (the labor force) and nonactive (not in the labor force). The labor force divides between employment and unemployment. A person is considered employed if he or she works at least an hour during the survey week. A person not working and actively searching for and willing to work is classified as being unemployed.

The official unemployment rate is the number of unemployed persons as a percentage of the labor force. While a rising rate usually indicates the economy is wasting resources and sacrificing income by not utilizing willing labor, it may also reflect a strengthening economy if the labor force is growing faster than employment.

International comparisons are difficult because countries vary the ILO definitions. However, the Organization for Economic Cooperation and Development (OECD) publishes standardized unemployment rates that reflect common definitions, and the U.S. Bureau of Labor Statistics publishes labor force statistics that convert foreign aggregates into estimates consistent with U.S. definitions.

HOW USEFUL IS THE OFFICIAL UNEMPLOYMENT RATE?

The official unemployment rate’s ability to portray accurately the condition of the labor market is challenged because it is a narrow measure of labor underutilization. Critics call for broader measures to be published. There are many issues relating to the labor force concept itself, including whether unpaid workers should be included in the labor force and whether defense personnel and persons who are institutionalized should be included in the working-age population. Decisions made by national statistical agencies with respect to these cohorts influence the size of the labor force estimate and in turn the unemployment rate estimate.

In this section we concentrate on the issues arising from marginal workers and underemployment. Total labor underutilization (wastage) of willing labor resources arises for a number of reasons that can be divided between two broad functional categories: (a) unemployment or its near equivalent, which includes the official unemployed under ILO criteria and those classified as being not in the labor force on search criteria (discouraged workers), availability criteria (other marginal workers), and more broadly still, those who take disability and other pensions as an alternative to unemployment (forced pension recipients). These workers share the characteristic that they are jobless and desire work if vacancies were available. They are, however, separated by the statistician on other grounds; (b) suboptimal employment relations, where workers are classified as being employed but suffer “time-related underemployment,” such that there are insufficient hours of work. Suboptimal employment also arises from an “inadequacy of the employment situation” when
skills are wasted, income opportunities denied, and/or workers are forced to work longer than they desire.

The official unemployment rate captures only a portion of this wastage. Broadening the concept of labor wastage involves recognizing other cohorts within the working-age population that share some similarities with the official unemployed.

First, focus on the rise of underemployment in many countries is increasing. While both sources of underemployment ("time-related" and "inadequacy of the employment situation") are possible to measure, in practice, estimates of time-related (or visible) underemployment are more easily obtained. Involuntary part-time workers face constraints similar to those confronting the unemployed. As estimated underemployment has risen around the globe, the official unemployment rate measured as the percentage of persons in the labor force not employed underestimates the extent of labor wastage. Governments that extol the virtues of employment growth generated under their watch rarely express it in terms of full-time equivalents and thus rarely admit that, in part, people are shifting from unemployment to underemployment.

Second, workers who are not working but have abandoned active search because they perceive there are insufficient job opportunities are classified as not in the labor force. These "hidden unemployed" or discouraged workers are similar to the official unemployed because they would accept a job offer immediately. They are also unlike others who are not in the labor force such as retirees.

A broad rule of thumb is that the true labor underutilization rate (including underemployment and hidden unemployment) is estimated by doubling the official unemployment rate.

We can consider two other working-age population cohorts that are less attached to the labor force but who nonetheless, by their size, provide some guide to the potential labor resources available to any country. First, persons who desire work but are unable to start immediately and are not actively searching are called marginal workers and are excluded from the labor force. But with some institutional changes (such as improved child or aged care) this cohort would accept immediate offers of employment. Second, in many countries the number of disability pension recipients has increased. These persons are excluded from the labor force on activity grounds. The increasing trend is arguably the result of health professionals and/or governments easing their interpretations of what constitute a disability when job prospects are low. Given that many of these persons are at the bottom of the labor queue (especially older males), pushing them out of the labor force reduces the unemployment rate and is thus politically beneficial in times of recession. In recent years, in strong employment-growth countries (for example, Australia) new measures have been introduced to induce this cohort back into the labor force in recognition that their disabilities may not preclude some capacity to work.

The justification for considering the broader underutilization concepts relates to the concept of labor efficiency. An economy that cannot provide enough hours of work to match the preferences of the available labor supply and/or institutional structures to maximize the participation of its potential labor resources is less efficient than one that can achieve these goals.

THE COSTS OF UNEMPLOYMENT

Is high unemployment a problem? Involuntary unemployment imposes heavy costs on the economy in the form of forgone output of goods and services and associated income. Economists typically ignore the social costs of unemployment. Unemployment also exacerbates social ills such as crime, family breakdown, and physical and mental health problems. Human capital (skills) atrophies when unemployment persists.

Strong spatial impacts reinforce the loss of income that accompanies unemployment. As a region's unemployment rate rises, more mobile workers (the youth and educated) leave such that skills are lost, making it hard to attract new business investment.

Many economists (mostly those who advocate a voluntarist conception) claim that unemployment is not a significant policy problem because it reflects the normal functioning of the labor market whereby job seekers use spells of unemployment to search for information about the career prospects that are available to them before settling into a career path. They specifically note that high youth unemployment is merely information-seeking behavior.

Focusing on short unemployment spells may be misleading given that many workers drop out of the labor force when they cannot find a job. Further, the transition by youth from a sequence of casual jobs to a higher paying career-oriented job is largely confined to those who combined schooling with casual employment while they acquire the skills necessary to satisfy entry into the chosen career path. While the casual work may have provided them with generic skills such as punctuality and grooming, the issue remains that those locked into the casual labor market and not combining work with schooling do not make such career transitions. Instead they sequence through a range of dead-end, low-paying jobs interspersed with spells of unemployment. For them unemployment provides no information.

WHAT CAUSES UNEMPLOYMENT?

Economists have used various taxonomies to help explain unemployment but remain in deep disagreement about its
causes. A major debate during the Great Depression centered on the extent to which unemployed individuals were acting voluntarily (classical position) or whether macroeconomic spending deficiencies imposed systemic constraints (lack of jobs) on individuals who become involuntarily unemployed (Keynesian position). Marx had earlier provided analysis supporting the demand-deficient explanation. In his 1936 General Theory, Keynes turned this idea into a full-blooded rejection of classical employment theory, and Keynesian theory subsequently dominated macroeconomics until the mid-1970s. It provides the most accessible unemployment taxonomy for the layperson by distinguishing between frictional, structural, and cyclical unemployment.

Jobs are continuously being created and destroyed as industries grow and wane, and these processes generate huge flows of workers moving between jobs. So even when demand for goods and services is strong, there will be a coincidence of unfilled vacancies and unemployed persons. This unemployment is called frictional because it arises from frictions that accompany job turnover. Workers take time to find and move to new jobs, and firms take time to locate required labor. While it clearly represents an irreducible minimum level, there is some confusion between this level of unemployment, which is likely to be low, and the concept of natural rate of unemployment, which is explained below. Both have been referred to as the irreducible level of unemployment.

Keynesian theory considers firms’ supply output and hires workers in response to the demand for goods and services. Demand-deficient or cyclical unemployment arises when the demand for labor overall (indicated by unfilled vacancies) drops below the number of workers who desire employment. The lack of jobs is experienced across all regions and industries. Cyclical unemployment reflects a systemic failure, with individuals powerless to improve their job prospects. Most economists agree that cyclical fluctuations in unemployment are caused by changes in the demand for labor rather than shifts in workers’ attitudes to work. As a result, most would agree that mass unemployment is involuntary. The policy solution to demand-deficient unemployment is to use expansionary fiscal and/or monetary policy.

The concept of structural unemployment sits uneasily within this framework. It reflects a mismatch between the requirements of available jobs and the characteristics of job seekers and arises even if there is no overall demand deficiency. This mismatch could be in terms of skills and/or locations and is of concern because the retraining and relocation of labor take time and resources. Structural mismatch may arise as changes in industry composition, reflecting changing consumer spending patterns, cause regional dislocation as growing industries seek new labor skills and declining industries shed skills. Adjustment is slow because the social settlement (where people live) is less mobile than the economic settlement (where jobs are created).

Technological change also creates skill obsolescence and a demand for new skills. A particular variant of this idea is found in the emergence in the 1970s of the deindustrialization literature, which focused on manufacturing decline (and to some extent the decline of mining) and the simultaneous rise of services. The amorphous concept of globalization is interwoven into these discussions to explain job loss in particular regions and industries as a result of employment being “exported” to lower cost regions and countries. If there is structural unemployment, expansionary policies will come up against bottlenecks and invoke inflationary impulses. Instead, training and mobility incentives are required to ease the mismatch. In this sense, structural unemployment is a microeconomic problem.

However, the boundaries between cyclical and structural causes are blurred. For example, theories of hysteresis conclude that the current state of the economy reflects where it has been. Accordingly, cyclical fluctuations create structural imbalances, which can be reversed through macroeconomic expansion. For example, recession generates skill obsolescence as old capital is scrapped and/or long-term unemployment causes skills to atrophy. This structural problem is reversed as the economy resumes growth because firms lower their hiring standards and provide training opportunities as a way around perceived skill shortages.

Clearly, the idea that individuals can experience involuntary outcomes underpins this taxonomy and overlaps with the voluntary/involuntary taxonomy that was central to the “Keynes versus Classics” debates in the 1930s and persists today. The Great Depression spawned macroeconomics as a new and distinct field of study, and center stage was the concept of involuntary unemployment, which challenged the neoclassical orthodoxy. The neoclassical competitive model postulated that the equilibrium unemployment rate is determined by the intersection of labor supply and demand, both functions of the real wage. As labor supply reflects workers’ preferences between labor and leisure (real wage is the opportunity cost of leisure) and labor demand reflects the marginal productivity of labor (profit-maximizing firms equilibrate the real wage with the marginal product), flexible real wages guarantee full employment. At the full employment real wage, any firm can find a suitable worker and any worker can find a suitable job. Any observed unemployment is deemed voluntary (worker preference for leisure). When the real wage is above the full employment level, the resulting unemployment is caused by real wage rigid-
ties such as excessive legislated minimum wages and trade union wage setting power.

This type of unemployment is termed classical and is solved by real wage cuts to restore the equilibrium level where labor demand equals labor supply. During the Great Depression, the government tried neoclassical remedies without success. In the 1930s, Kaleck and Keynes, building on the earlier work of Marx, challenged this dominant view. They saw mass unemployment as a systemic failure in demand for goods and services—that is, cyclical. Deficient effective demand causes firms to lay off workers. Neoclassical remedies would exacerbate this Keynesian unemployment because real wage cuts reduce worker incomes, further eroding effective demand. As firms adjusted to the lower activity by producing and employing less, an exogenous force in the form of expansionary fiscal and/or monetary policy was needed to push the economy toward higher activity levels.

Keynesian unemployment is involuntary because an individual unemployed worker cannot improve his or her job prospects in the face of employment rations imposed by deficient effective demand. This concept challenges the centerpiece of neoclassical theory known as Say's law, which holds that aggregate demand always absorbs production, given price flexibility. Keynes showed that even with flexible prices, unemployment would persist until the deficient demand was eliminated. This observation underpinned the so-called Keynesian revolution that dominated the next thirty years of policy making. The period of full employment up until the mid-1970s gave policy makers confidence that the business cycle had been tamed.

Neoclassical economists argue that the concept of involuntary unemployment is implausible because it implies irrational behavior by individuals. Why would workers not simply accept lower real wages? Keynesians respond by arguing that workers prefer higher money wages at each real wage level because they have large nominal commitments (such as mortgages). Resisting a money wage cut was rational even if real wages were falling (via general price-level rises) because nominal commitments could be maintained. Keynesians also argue that workers are unable to engineer a real wage cut by accepting a lower money wage because the lower costs would lead to competitive price-cutting with no guarantee of a lower real wage. But this was moot because even if real wages fell, firms would still not hire if the cheaper labor produced goods and services that could not be sold (given deficient demand).

The major policy challenge for Keynesians in a period of full employment was inflation as economies approached full capacity. A vast literature has emerged since the late 1950s examining the relationship between the unemployment rate and inflation—the so-called Phillips curve (Phillips 1958). Policy makers came to believe that they faced a stable trade-off between the twin evils of unemployment and inflation and sought to choose the combination that maximized social welfare.

The challenge to the Keynesian macroeconomic consensus was ignited by the “monetarist” contributions of Friedman (1968) and Phelps (1967). They disputed the existence of a stable Phillips curve that could be exploited using aggregate demand policy. For example, the misperceptions hypothesis (Friedman 1968) considers that workers possess less short-run information than employers about the relationship between relative and absolute price levels. Accordingly, workers can be induced to supply more labor than is optimal given their preferences for as long as they are confused about their real wage level. They thus believe that a nominal wage rise is a real wage rise and supply more labor accordingly. Once they learn the truth, they withdraw this supply and equilibrium is restored. So any policy-induced reductions in the unemployment rate bought by tricking workers into supplying more labor than was optimal would evaporate. The long-term implication was that there is a “natural” unemployment rate that reflects the underlying microeconomic structure of labor supply and labor demand, and any attempts by fiscal and monetary authorities to drive unemployment below this equilibrium generate ever increasing rates of inflation.

The essence of all supply-side explanations is that workers quit when times are bad despite all evidence to the contrary. The pro-cyclical nature of quitting challenges the very core of the neoclassical labor market model.

However, the rising inflation associated with the Vietnam War and the oil price hikes in the early 1970s provided a fortuitous empirical backdrop to the growing backlash against Keynesian demand management policies. While there was scant empirical support to associate rising inflation with the mechanisms that underpinned the natural rate hypothesis, the revival of Say's law was broadly accepted by economists and policy makers.

Keynesians such as Clower (1965) and Leijonhufvud (1968) provided resistance to the natural rate hypothesis by showing that no market signals accompanied mass unemployment such that firms would hire more workers, even though these workers had notional demands for their products. The problem was that without income these demands were not effective. The market coordination implicit in Say's law failed in these situations, leaving the economy stuck in an under-full-employment equilibrium.

By the 1970s, the “new labor economics” reinstated neoclassical notions of voluntarism in explaining unemployment, a view that still dominates labor market policy today. Accordingly, unemployment arises from workers'
need to search for new jobs and jobless spells are voluntary, maximizing strategies in pursuit of career improvement. Workers balance the costs of search (time and forgone earnings) with the gains in future earnings that emerge from successful search. Importantly, welfare benefits are seen as subsidizing search and encouraging long-term unemployment.

The reality is that while most job search activity is done on the job, many unemployed workers experience frequent spells of unemployment interspersed with low-skill, low-paid employment. Segmented labor market theory uses this observation to argue that structural rigidities, principally due to hiring policies of employers, discriminate against disadvantaged groups and confine them to marginal jobs and status (Doeringer and Piore 1971).

MODERN DEBATES ABOUT CAUSES OF AND REMEDIES FOR UNEMPLOYMENT
The breadth of the acceptance of the new labor economics by economists and policy makers was expressed in the influential 1994 OECD Jobs Study, which provided a policy blueprint for economic policy reform aimed at reducing unemployment following the deep recession in 1991. Its theoretical foundations can be found, for example, in Layard, Nickell, and Jackman (1991), LNJ for short. While, economists such as LNJ mimicked the traditional neoclassical concern about trade union power and legislated minimum wages, they also focused on welfare payments as a cause of persistent unemployment. They argued that the provision of unemployment assistance subsidized inactivity by reducing the intensity and effectiveness of job search. As a result of this subsidy, the wage necessary to induce the worker to abandon unemployment and accept work (the so-called reservation wage) is higher. Further, various government charges on employment (such as superannuation and termination payments) drive a wedge between what the worker receives and what the firm pays, which discourages firms from increasing employment. It was also argued that the long-term unemployed had deficient skills and required retraining to improve their employability.

The Jobs Study concluded that long-term unemployment was the outcome of government intervention, other institutions (such as trade unions), and/or negative attitudes to work of the unemployed that created rigidities in labor supply. The Jobs Study advocated extensive supply-side reform with a particular focus on the labor market to eliminate rigidities that were inhibiting the capacity of economies to adjust, innovate, and be creative. Governments variously adopted the reform agenda. It was typically accompanied by a narrowing of the focus of monetary policy to inflation control, which used unemployment as an instrument to achieve price stability rather than as a policy target. Further, governments adopted fiscal conservatism (for example, the Stability and Growth Pact in Europe) to passively support their inflation-first monetary policy emphasis. Policy makers believed that disinflation policy would allow the economy, after an adjustment phase, to settle at the natural rate optimum, and as a consequence they did not worry about any alleged “short-run” negative impacts of disinflation on unemployment. They considered that the micro focus of the Jobs Study would ensure there were no impediments to reaching this supposed natural rate.

However, high unemployment persisted in many countries during the 1990s, which prompted critics of the OECD position to say that governments had been encouraged to abandon full employment in favor of full employability. The critics said that unemployment existed long before unions had grown and welfare transfers operated. They also said that it was implausible to interpret the mass unemployment of the Great Depression as a sudden labor supply withdrawal.

In recent years, partly in response to the reality that active labor market policies have not solved unemployment and have instead created problems of poverty and urban inequality, some notable shifts in perspectives are evident among supporters of the OECD approach. Various econometric studies sought to establish the empirical veracity of the OECD Job Study relationships between unemployment, real wages, welfare payments, and the like. They also sought to evaluate the effectiveness of active labor market program spending. Many construct their analyses in ways that are most favorable to the null that the OECD view is valid. The overwhelming conclusion to be drawn from this literature is that there is no consensus view (see Freeman 2005; Baker, Glyn, Howell, and Schmitt 2005).

In the face of the mounting criticism and empirical argument, the OECD has now significantly shifted its position. In the 2004 OECD Employment Outlook, it admitted that the evidence underpinning the neoclassical relationship between real wages and unemployment was fragile. In the 2006 OECD Employment Outlook, which followed a comprehensive econometric study of employment outcomes across twenty OECD countries between 1983 and 2003, the OECD (2006) found that:

- There is no significant correlation between unemployment and employment protection legislation;
- The level of the minimum wage has no significant direct impact on unemployment; and
- Highly centralized wage bargaining significantly reduces unemployment.
These conclusions undermine the basic causality in the Jobs Study. They also confound those who have relied on the OECD’s previous work, including the Jobs Study, to push through harsh labor market reforms, retrenched welfare entitlements, and policies aimed at reducing the role of trade unions.

Internationally, sentiment is growing that paid employment measures must be a part of the employment policy mix if unemployment is to be reduced. The lack of consideration given to job creation strategies in the unemployment debate stands as a major oversight. Recognition is growing that programs to promote employability cannot, alone, restore full employment and that the national business cycle is the key determinant of regional employment outcomes (Mitchell 2001; Peck 2001).

UNEQUAL DEVELOPMENT

SEE Unequal Exchange.

UNEQUAL EXCHANGE

The liberal theory of free trade based mainly on the theory of comparative advantage is regarded as a win-win situation without any limitations. During the 1950s, however, development theorists presented a challenge to this well-established neoclassical theory. The theory of unequal exchange is a reaction to the naïve theory of comparative advantage. It provides a Marxist notion of the exploitation that is embedded in the comparative advantage theory.

The development of the theory of unequal exchange has followed several directions. First, some writers, including Andre Gunder Frank in Capitalism and Underdevelopment in Latin America (1967), argued that comparative advantage is not a natural endowment; rather, it is created by historical power relations through the exploitation of nations.

Second, some researchers examined the distributional inequalities of trade. Thus, the Prebisch-Singer thesis reveals that the terms of trade work against developing countries. This well-known issue of dependency theory was systematically developed in the 1950s (Ghosh 2001).

Third, on the basis of assumptions of the restricted mobility of labor and the perfect mobility of capital, Arghiri Emmanuel (1969) formally developed the theory
of unequal exchange. He argued that under a situation of perfect competition, trade between developed and developing countries involves a transfer of surplus from the latter countries. In a situation of equal productivity in developed countries (DCs) and less developed countries (LDCs), but lower wages in the LDCs, high-priced products of the DCs are exchanged for low-priced products of the LDCs. Hence, the exchange is unequal. Emmanuel noted that since wages are institutionally determined, they are exogenous to the model. However, in DCs, trade unions have a critical role in raising wages. But this is not the case in LDCs. In the process of unequal exchange, there is a transfer of value from a country with low capital intensity (often a developing country) to a country with high capital intensity in production (as in a typical developed country).

Emmanuel, an Italian Marxist, has used the Marxian theory of transformation of value into prices to show that LDCs are compelled to sell their goods at prices below their value and to purchase goods from DCs at prices above their value. In the process, the advanced countries appropriate more labor time than they generate in production. In other words, DCs can get commodities from LDCs at lower prices than would have been available in their own countries. In this process of exchange, LDCs stand as losers, and DCs as gainers.

Emmanuel's analysis has been subjected to severe criticism by many scholars, including Paul Samuelson, who tried to demonstrate that the argument developed by Emmanuel is preposterous. According to Samuelson, Emmanuel concentrated simply on the circulation sphere and failed to recognize the productivity differentials between core and peripheral countries. Emmanuel is also criticized on the grounds that he treated wages as an exogenous variable.

Samir Amin (1970) presented a new version of unequal exchange by considering wages as an endogenous variable, and he showed that unequal exchange allowed capitalist countries to protect profits. To him, the dominance of foreign capital in LDCs means distorted export activity and the hypertrophy of the tertiary sector. Peripheral countries thus incur heavy debts to core countries, become necessarily dependent on them, and become linked with the world capitalist system.

In the new world order, trade is organized largely by powerful multinational companies without any regard for small peasants and poor workers. The social cost of trade in terms of damage to the environment and human rights is much greater in LDCs. Even in a situation of trade based on comparative advantage, the gains from trade are not equally distributed. Because of the many structural differences between the LDCs and the DCs, factor price equalization is not possible. Domestic wages are falling in LDCs due to the race to the bottom and the informalization of labor markets (Ghosh and Guven 2006). The advantage of productivity gains through higher wages has never trickled down to LDCs through the channel of trade. Unequal competition and dissimilar bargaining powers between these two groups of countries make the theory of unequal exchange still relevant.

UNICAMERALISM
SEE Bicameralism.

UNIDENTIFIED FLYING OBJECTS
Any discussion of unidentified flying objects (UFOs) invokes multiple, often contradictory, meanings. In popular culture the UFO is an emblem of atomic-age anxiety and desire. Nonetheless, there were unidentified airship sightings in late nineteenth century America and scholars have documented striking parallels between UFO encounters and traditional fairy lore. Some UFO believers describe UFOs as prophetic missives from spiritual realms while other equally passionate believers locate UFOs in scientific and political quests.

An aura of marginality is an essential feature of UFO believers. Simultaneously, however, fascination with UFOs is mainstream. A 2002 Roper poll sponsored by the Science Fiction Channel suggested that a majority of
Americans believe in the existence of UFOs. Groups based on interest in UFOs (such as the research oriented Mutual UFO Network; support groups for alien abductees; and Internet communities) encompass multiple aesthetic and epistemological affinities spanning generational, class, racial, and geographic boundaries. Interpretations of UFOs are made to fit into larger patterns of belief ranging from anti-government conspiracies to Christian eschatology (i.e., the end of the world). UFOs are said to be involved in unknown phenomena such as mysterious patterns appearing in grain fields—crop circles—and cattle mutilation. Perhaps the only fixed feature of the UFO is its openness as a symbol; always remaining “unidentified” has made the UFO an icon for uncanny elements of life in a rationalized age.

A major theme in UFO discourse is the paucity of official scientific research into extraterrestrial visitation. (UFOlogy is the study of UFOs.) Reports of UFO encounters have been studied through official venues, though these results tend to further the division between UFOlogy practiced by amateurs and authoritative forms of power and knowledge. In 1947 the Army Air Force began one of three investigative studies into reported UFO sightings. The final investigation, Project Blue Book, ended in 1969 with the conclusion that natural phenomena accounted for most UFO sightings. As with many UFO-related conclusions, however, this one remained open. One of its own participants, astrophysicist J. Allen Hynek, was dismayed by the investigation’s lack of scientific rigor and open-mindedness, especially regarding ambiguous reports that could not be explained as natural phenomena ([1972] 1998). Hynek assumed the rationality of most UFO witnesses and renounced his initial skepticism to become a major figure of UFOlogy.

In social science UFO belief has been studied for insights into religion, memory, psychology, and culture. Scholars of “new religions” make no claim as to the reality or falsity of UFOs but track religions or “cults” that arise out of the belief. In recent studies in psychology and memory at Harvard, researchers found abduction memories were linked to common brain states between sleeping and waking (Clancy 2005). Scholars in anthropology and cultural studies have also studied UFOs in the context of larger social and cultural meanings (Dean 1998, Battaglia 2005). Beginning with psychologist Carl Jung (1875–1961) to the beginning of modern UFO belief in the mid-twentieth century, scholars of psychology, religion, and culture emphasized the mythic elements of UFO belief. UFO history itself is organized through large stories of events that come to function like origin myths. Such narratives include the “first sighting,” the “first crash” and the “first abduction.”

THE “FIRSTS”: ORIGIN NARRATIVES

UFOs are often said to enter American life through Kenneth Arnold, a respectable businessman and pilot who was flying solo in Washington State on a clear afternoon, on June 24, 1947. After Arnold saw nine unidentifiable objects flying over the Cascade Mountains he told a reporter the objects moved in the sky like saucers, thus coining a lasting term. Although other strange flying objects had been reported in the year before Arnold’s sighting, his sighting became the originary narrative of UFO culture and was the impetus for the military’s first UFO investigations. In the U.S. government, there was worry about both extraterrestrials and a possible secret weapon in development. From this beginning, UFOs were entangled with technological military development.

Weeks after Arnold’s sighting a crashed flying saucer was reported from Roswell, New Mexico, the only military base with an atomic bomb unit. A rancher named Mac Brazel had discovered mysterious wreckage scattered over the countryside, including pieces covered in what appeared to be hieroglyphics. Sometime in the next few days, amid the excitement of flying saucer talk around America, Brazel reported his find to the local sheriff, who in turn reported it to the Army Air Field’s (AAF) intelligence officer, Jesse Marcel. The AAF issued a press release that led the Roswell Daily Record to report on July 8 that a flying saucer had been captured by the Air Force near Roswell. But within a day, Brigadier General Roger Ramey called the press, changing the UFO explanation to that of a crashed high-altitude weather balloon.

STORIES OF CONSPIRACY

The incident receded. Its uncanny and conspiratorial elements emerged in the late 1970s when Stanton Friedman, a UFO researcher with a background in nuclear physics, happened to meet Marcel and began to investigate the case. Friedman claimed that the government had been hiding evidence of this crashed UFO for decades. In subsequent research by Friedman and other researchers, one part of the story grew especially salient: Alien bodies had been recovered and hidden by the government for research. Reports grew of the military threatening witnesses. Friedman used testimony from a recently-emerged witness to propose that two extraterrestrial crafts had crashed in the area, and the government had secreted the crafts along with the alien bodies. In another twist, a former Pentagon official and army colonel named Philip Corso claimed not only that he had seen alien bodies from the Roswell crash but that the United States had developed modern technology, such as the integrated circuit and the laser, by studying the extraterrestrial craft. There was speculation that the UFOs had made their way to
Area 51, a top-secret high technology military base bordering the Nevada nuclear test site.

In 1994 Representative Steven Schiff of New Mexico requested the release of government files on Roswell under the Freedom of Information Act. To Schiff, the files were unsatisfactory, containing scant and redacted pages. Finally, however, Schiff’s appeals to the Congressional General Accounting Office led to revelations about a secret cold war program in 1947 called Project Mogul. Scientists from New York University had launched balloons in New Mexico carrying devices meant to track nuclear tests by the Soviet Union. One of these had disappeared near Roswell during the appropriate time period. The balloons had some of the physical qualities described by witnesses fifty years earlier, such as tape containing symbols that could have been mistaken for alien hieroglyphics. This explanation has created controversy among UFO researchers, some of whom are convinced and some of whom still believe in the extraterrestrial hypothesis.

The original story of the first abduction contained themes that set a pattern for subsequent cases. In September 1961 a couple from New Hampshire named Betty and Barney Hill experienced “missing time” while driving in the White Mountains. Strange dreams and Barney’s anxiety prompted them to seek out hypnotherapy, which revealed memories of having been abducted. According to the Hills, the couple had seen a UFO approaching and their car engine had failed. Like most alleged abductees, the Hills described a medical violation of their bodies, especially their sexual organs.

ABDUCTION PATTERNS

Since the case of the Hills, many abduction narratives have followed a similar pattern of clinical experimentation and violation based on human reproduction. Some people recall seeing “hybrids,” offspring between humans and extraterrestrials.

Budd Hopkins (1981) and David Jacobs (1992) have been at the forefront of this narrative’s circulation for twenty years, often relying on hypnosis to elicit traumatic abduction memories. Symptoms of abduction that might lead one to seek hypnotic regression include missing time, unexplained marks on the body, unexplained mechanical failures, strange dreams, and “screen memories” of things representing extraterrestrials. In one famous case, logger Travis Walton says he was abducted from Arizona by extraterrestrials for several days. In most instances documented by Hopkins and Jacobs, however, the missing time is hours, not days, and there are rarely witnesses.

While many people who claim to be abductees portray abductions as terrifying, it is often more complex. A belief in benevolent spiritual extraterrestrials, prevalent in the mid-twentieth century, became an ambivalent, complex discourse of personal transformation. The process of post-traumatic spiritual enlightenment undergone by “alien abductees” is best known from the work of two men: Whitley Strieber, who in the 1980s turned from writing best-selling science fiction and fantasy novels to writing a nonfiction account of his own encounters with extraterrestrials; and John Mack, a Harvard psychiatrist who, late in a distinguished academic and clinical career, began working with people who said they had memories of alien abduction and experienced great spiritual growth.

UNIFORM BERTRAND’S PARADOX
SEE Distribution, Uniform.

UNILATERALISM
The term unilateralism describes an approach toward conducting foreign policy in which a country does not subordinate its aims or actions to the wishes of other countries or the constraints of international agreements. While few would advocate discarding all multilateral commitments, there is disagreement over the degree to which a country (and especially, a hegemon like the United States) ought to pursue its foreign policy in a unilateral fashion.

Although the debate over unilateralism became heated during the administration of President George W. Bush, the concept has a long history in U.S. foreign policy. In his 1796 farewell address, President George Washington (1732–1799) urged the United States to “steer clear of permanent alliances with any portion of the foreign world, so far … as we are now at liberty to do it.” Advocates of unilateralism emphasize that such a policy does not imply isolationism. Nor does it imply that the ends sought by a country are narrowly defined or that they neglect the interests of other countries. Indeed, Charles Krauthammer celebrates a “new unilateralism” that, he argues, “is clear in its determination to self-consciously and confidently deploy American power in pursuit of … global ends” (2002/2003, p. 14), such as promoting democracy and maintaining peace and stability. In this view, the hegemon has unique responsibilities in managing the international system that other states may not share or even support.

Countries with less power naturally seek to restrain the hegemon. Robert Kagan, for instance, argues that “Europe’s military weakness has produced a perfectly understandable aversion to the exercise of military power” (2002, p. 10). Ideology, economic interests, domestic politics, or honest disagreement about the wisdom of a particular policy may also lead smaller powers to oppose the hegemon’s unilateralism. As a result, there may simply be little the hegemon can do to assure smaller countries. Furthermore, American unilateralists argue that the United States should not, as President Bush remarked in his 2004 State of the Union address, “seek a permission slip to defend the security of our country.”

A unilateral approach does not shun allies, but it counsels against adjusting one’s policies to accommodate the views of other states. As U.S. Secretary of Defense Donald Rumsfeld said in 2002: “The mission must determine the coalition, and the coalition must not determine the mission. If it does, the mission will be dumbed down to the lowest common denominator, and we can’t afford that.” According to Rumsfeld, exercising strong leadership will eventually bring countries on board. As Krauthammer argues, “no one wants to be left at the dock when the hegemon is sailing” (2002/2003, p. 17).

By contrast, critics argue that acting unilaterally reduces a country’s ability to achieve its interests and increases the associated costs of its foreign policy. Part of the reason why unilateralism is such an inefficient way to achieve national goals lies in its lack of legitimacy. As a result, other states will be less likely to support or cooperate with such policies, reducing the probability of success. Power is less costly to exercise when it takes the form of authority, combining power with consent from others. Moreover, other countries find a hegemon’s unilateralism threatening and are thus more likely to balance against it. By contrast, multilateralism signals that a state is taking the interests of other countries into account in formulating its own foreign policy; this poses less of a threat to other countries and reduces the chances that they will align against the hegemon. Although there is much debate over whether such counterbalancing occurs, survey evidence makes clear that the United States is perceived by much of the world as acting unilaterally and that this has generated widespread resentment since the late 1990s.

Advocates of unilateralism answer critics by pointing out that while there may be costs to unilateralism, there are also costs to multilateralism. John Bolton, the U.S. ambassador to the United Nations during George W. Bush’s second term, argued that “the costs [of multilater-
alism] to the United States—reduced constitutional autonomy, impaired popular sovereignty, reduction of our international power, and limitations on our domestic and foreign policy options and solutions—are too great, and the current understanding of these costs far too limited to be acceptable” (Bolton 2000, p. 221). Similarly, in an overview of the case against unilateralism from the standpoint of international relations theory, Stephen G. Brooks and William C. Wohlfforth (2005) argue that most scholars oppose unilateralism on substance grounds and have provided only weak theoretical reasons to criticize the approach on more general procedural grounds.

In economic relations, the term unilateralism is used more specifically to refer to trade policies, frequently carried out by the United States during the 1980s and 1990s, that involve imposing sanctions on countries whose markets are deemed to be closed to foreign products. Proponents of this approach argue that only this pressure can pry open previously closed markets; thus, unilateralism could increase the total amount of international trade and improve world welfare. In particular, they argue that countries such as Japan that are characterized by structural or informal trade barriers often do not respond to multilateral rules and thus require more forceful measures—such as results-oriented managed trade—to break into their markets.

Critics of so-called aggressive unilateralism, such as Jagdish Bhagwati (1990) and Douglas A. Irwin (1994), respond by questioning whether in fact these countries are really acting “unfairly.” To the extent that powerful countries, responding to domestic pressure, threaten sanctions against allegedly closed markets, the targeted state might respond by satisfying the complaining state, thereby diverting trade from countries with less political clout. The result would thus not be more trade, but rather discrimination in favor of the powerful. Within the target country, the power of bureaucrats would be expanded rather than reduced—an effect that would slow down the country’s integration into the world trading system. Most seriously, when powerful countries determine for themselves whether other states are acting unfairly, the rule of law in the international trading system is undermined. As Bhagwati writes, “the world trading regime should not be built on the assumption that any one player, no matter how dominant, can impose its own rules, unilaterally claiming social legitimacy for them” (1990, p. 36). In fact, the spread of this policy was an important factor in building support for the creation of a stronger World Trade Organization (WTO). Since the creation of the WTO, such resorts to unilateralism have declined. Nonetheless, as the controversy over antidumping duties suggests, the issue has by no means disappeared.

UNION OF SOVIET SOCIALIST REPUBLICS
The Soviet Union was the world’s first Communist state, the West’s principal adversary during the cold war, and a dominant force in international affairs until its collapse in 1991. Moreover, the Soviet Union was the world’s largest country stretching from the Baltic and Black Seas to the Pacific Ocean. It also had over one-hundred distinct nationalities living within its borders, making it extremely diverse. Thus, it is not surprising that almost every social science subfield devoted much time and effort to studying various aspects of the Soviet Union. This makes the amount of social science research produced on it almost impossible to quantify.

The history of the Soviet Union begins with the Russian Revolution of 1917. In February of that year the wartime decay of Russia’s economy and morale triggered a
spontaneous popular uprising in Petrograd. This culmi-
inated in the imperial government of Czar Nicholas II
(1868–1918) being overthrown. After the formation of a
provisional government, workers councils, known as sovi-
ets, began to sprout up throughout the country to protect
the rights of the working class. This allowed the
Bolsheviks (Communists) to arouse widespread interest in
a socialist revolution. Eventually, in November 1917, the
Bolsheviks, led by Vladimir Lenin (1870–1924), seized
power from the provisional government and established
the world’s first Communist government.

Immediately after the Bolsheviks came to power a
civil war erupted between the Communist Red Army and
the loosely allied anti-Communist White Army. Despite
struggling for survival throughout the bitterly fought civil
war, there was no doubt that the Communists would
emerge victorious by the end of 1920. Finally, after secur-
ing power, the Bolsheviks officially established the Soviet
Union in December 1922. Lenin, as head of the party,
became the de facto ruler of the country.

Under Lenin, the new government centralized its
control over the political, economic, social, and cultural
lives of the Soviet people by prohibiting other political
organizations and inaugurating one-party rule. However,
Lenin realized that a radical approach to communism did
not suit existing conditions and jeopardized the survival
of his regime. In turn, under the program that came to be
known as the New Economic Policy, the state sanctioned
partial decentralization of the economy; market forces and
the monetary system regained their importance, but heavy
industry remained under state control.

As the Communist Party continued to consolidate its
authority throughout the country, it became a monolithic
presence. However, in May 1922 after Lenin became tem-
porarily incapacitated by a stroke, the unity of the
Communist Party fractured. This facilitated Joseph
Stalin’s (1879–1953) rise to power, and he became general
secretary in April 1922. Lenin’s death in January 1924
cemented Stalin’s dominance over the Politburo, the exec-
utive committee of the Communist Party.

THE STALIN ERA
Transformation and terror best characterize the first
decade of Stalin’s rule. Beginning in the late 1920s, Stalin
began carrying out a program of intensive socialist con-
struction by rapidly industrializing the economy and
nationalizing all industry and services. At the same time,
Stalin began purging from the Communist Party all lead-
ers and their followers deemed disloyal. The most promi-
nent leader was Leon Trotsky (1879–1940), a Bolshevik
revolutionary and a founding member of the Politburo.

Soviet foreign policy also underwent a series of
changes. Lenin realized that the Soviet government
required normal relations with the Western world for it to
survive. Stalin, by contrast, aimed to exasperate social ten-
sions in Europe to produce conditions favorable to
Communist revolution. Nevertheless, the dynamics of
Soviet foreign relations changed drastically after Stalin rec-
ognized the danger Nazi Germany posed. In turn, to con-
strain Germany, the Soviet Union built coalitions that
were hostile to fascism. Furthermore, it gave assistance to
antifascists in the Spanish Civil War (1936–1939).

After France and Britain acquiesced to Adolph
Hitler’s (1889–1945) demands for Czechoslovak territory
at Munich, Germany, in 1938, Soviet foreign policy
shifted again; Stalin decided to come to an understanding
with Germany. This culminated in the Nazi-Soviet
Nonaggression Pact of August 23, 1939, which called for
absolute neutrality in the event one of the parties became
involved in war. However, after World War II
(1939–1945) broke out, Hitler began preparing for war
against the Soviet Union. Germany finally declared war
on the Soviet Union in June 1941. Although the Great
Patriotic War, as World War II was referred to in the
Soviet Union, began inauspiciously for the Soviet Union,
the war with Germany ended triumphantly for the
Soviets.

The Soviet Union rebuilt its economy during the
immediate postwar period and continued to maintain
strict centralized control over state and society. It also
emerged from the war as a world superpower along with
the United States. In turn the Soviet Union began taking
an active role in the United Nations as well as in other
major international and regional organizations. However,
as it turned many Eastern European countries into satel-
lite states and set up the Warsaw Pact and Comecon (eco-
nomic and military organizations of Central and Eastern
European Communist states), the Soviet Union’s relations
with the West became extremely tense. This led to the
protracted geopolitical, ideological, and economic strug-
gle between capitalism and communism known as the
cold war.

FROM STALIN’S DEATH TO
GORBACHEV’S REFORM
Stalin died on March 5, 1953. Since Stalin did not name
an heir, a factional power struggle broke out within the
party. After the succession struggle abated, Nikita
Khrushchev (1894–1971) emerged as first secretary. By
the beginning of 1956, Khrushchev was the most impor-
tant figure within the Soviet leadership. Khrushchev even
denounced Stalin and launched a campaign to ease
the repressive controls over party and society. But,
Khrushchev did face significant opposition in the
Presidium, or Politburo, which threatened much needed
economic reform and the de-Stalinization campaign. The
Presidium even voted Khrushchev out of office in June 1957, but the Central Committee (the highest body of the Communist Party of the Soviet Union to which the Politburo reported to) overturned the decision and expelled Khrushchev’s opponents. After becoming prime minister in March 1958, Khrushchev’s position in the state and party was solidified.

Khrushchev attempted to carry out domestic reform in a range of fields, but economic difficulties and political disarray remained. At the same time, events such as the suppression of democratic uprisings in Hungary and Poland in 1956 hurt the Soviet Union’s international stature. Furthermore, Khrushchev’s efforts to improve relations with the West suffered many setbacks, especially after the Cuban Missile Crisis (a cold war conflict between the United States and the Soviet Union regarding a Soviet buildup of nuclear missiles in Cuba). These events highlighted the fact that Khrushchev never exercised the high level of authority that Stalin did.

In October 1964 the Presidium voted Khrushchev out of office again. Khrushchev’s removal from office was followed by another period of rule by collective leadership. During this time, the Soviet leadership experimented with economic reform and several individuals contended for power. This situation lasted until Leonid Brezhnev (1906–1982), who attained the post of first secretary in 1964, became the most important figure within the Soviet leadership in 1971. During Brezhnev’s sixteen years as first secretary, economic and political reform was nonexistent. The Soviet Union also stepped up its repression against political dissidents and even tolerated popular expressions of anti-Semitism.

Soviet relations with the West first improved in the years after Khrushchev, which led to détente, or a relaxing of strained relations, in the early 1970s. Although the international community viewed this as a positive development, the use of force in Eastern Europe to suppress reform movements, attempts to broaden its influence in the Middle East, and its expanding influence in the developing world in accordance with the strategy of non-alignment caused improved relations to be short-lived. Finally, détente appeared dead when Brezhnev sent armed forces into Afghanistan in December 1979 to shore up the Communist government there. This along with economic stagnation proved to be formidable challenges for the Soviet leadership after Brezhnev’s death in 1982.

After the rapid succession of Yuri Andropov (1914–1984) and Konstantin Chernenko (1911–1985), the reform minded Mikhail Gorbachev (b. 1931) became general secretary in March 1985. To fix the crumbling Soviet political and economic structures, Gorbachev implemented the perestroika program to improve living standards and worker productivity and glasnost, which freed public access to information after decades of government regulations. This reinvigorated détente allowed Gorbachev to develop a strong relationship with President Ronald Reagan (1911–2004) of the United States. However, the impact the policies had on the Soviet Union’s political and economic structures was not so positive.

THE SOVIET UNION’S DEMISE

Although there is debate over what exactly caused the Soviet Union’s demise, it is clear that the policies of perestroika and glasnost led to unintended consequences that greatly contributed to this. This is because the relaxation of censorship on the media brought to light many of the severe social and economic problems the Soviet government claimed did not exist; events such as the ongoing war in Afghanistan and the Chernobyl nuclear power plant disaster in 1986 exasperated this. These negative aspects of Soviet life, in turn, undermined the faith of the people in the Soviet system and eroded the Soviet Union’s identity and integrity. Moreover, improved relations with the West infuriated Soviet hardliners.

This led to upheaval throughout the Soviet Union and in its Eastern European satellite states. In the late 1980s nationalism was rising throughout the Soviet republics, which reawakened ethnic tensions throughout the Union thereby discrediting the idea of a unified Soviet people. The Soviet Union, in turn, lost all control over economic conditions. At the same time, Moscow disowned the Brezhnev Doctrine in favor of nonintervention in the internal affairs of its Warsaw Pact allies. This was significant given that the Brezhnev Doctrine had modeled Soviet foreign policy since 1968; the Brezhnev doctrine stated that if any hostile force tried to turn the development of any socialist country towards capitalism, it would become the problem and concern of all socialist countries. Eventually, many Soviet satellite states began asserting sovereignty over their territories with some even declaring independence. By 1991 revolution had swept through Eastern Europe bringing down several Communist governments.

In February 1990 the unintended consequences of Gorbachev’s reforms forced the Central Committee of the Soviet Union to give up its monopoly of power. Even though the Communists were not going down without a fight, a unionwide referendum saw approximately 78 percent of voters approve the retention of the Soviet Union in an altered form. Presidential elections followed in June; Boris Yeltsin defeated the Gorbachev-backed Nikolai Ryzhkov.

Gorbachev attempted to restructure the Soviet system into a less centralized state. But in August 1991, the vice president, prime minister, defense minister, KGB (the Soviet security agency) chief, and other senior officials...
acted to prevent the signing of the union treaty. The coup organizers put Gorbachev under house arrest at his vacation home in the Crimea and attempted to restore the Union to its former state. However, public sympathy for their actions was largely against them and the coup ultimately failed. After the coup the Soviet republics accelerated their process toward independence. Finally, on December 8, 1991, Soviet leaders decided to dissolve the Union and established the Commonwealth of Independent States, which is an alliance that is open to all former Soviet republics. The Soviet Union ceased to exist by the end of December.

BEYOND THE SOVIET IMPERIUM

The dissolution of the Soviet Union led to numerous political, economic, and social changes within the region. Democratization and economic liberalization began throughout the post-Soviet sphere. However, the transition from communism in the former Soviet Union only sometimes led to democracy; some states abandoned communism for democracy, while others turned to authoritarian rule. Many of the post-Soviet republics also saw their economies collapse during the transition to capitalism. Corruption, weak property rights protection, and political instability were just a few of the reasons for this. Russia, in particular, struggled in its transition to a market economy. This precipitated a return to more interventionist economic policies by the government. Further, numerous ethnic and religious conflicts erupted. There are a number of de facto, but internationally unrecognized, states as a result of this.

Several global changes that have occurred since the Soviet Union’s demise are also worthy of note. There are no longer two clear-cut superpowers dominating international political life. Nuclear disarmament and reconfigured security arrangements are the salient themes in this “new world order.” Economic interdependence and political integration are also being seen everywhere. However, the most important global change since the Soviet Union’s demise is the ever-increasing threat of terrorism, especially Islamic fundamentalism. The events of September 11, 2001, indicate that this has officially replaced nuclear war as the greatest threat to peace.

There is no doubt that the Soviet Union was one of the most powerful countries in the world during its period of existence, especially from 1945 to 1991. At its peak it consisted of fifteen republics making it one of the most strongly centralized federal unions in the history of the world. Furthermore, the Soviet Union became a primary model for future Communist states; some states, such as Cuba, exemplify the Soviet tradition. All of this suggests that it is likely that few topics will generate as much social science research as the Soviet Union did.

UNION SHOP

SEE Labor Law.

UNIONS

Unions are organizations of wage earners designed to better working conditions and give laborers a collective voice in the contract bargaining procedure.

Unions emerged from the early trade associations built by workers confronting the effects of the industrial revolution. In 1790, New York City was a center of commerce, but not yet an industrial city. It was also a city
divided by class, property, and power. On the one hand, a wealthy class of traders and financiers had developed during the pre-revolutionary period and controlled the city's international commerce. They were merchant capitalists who made their money through import and export, buying commodities cheaply in Europe, Asia, Africa, and the Americas, and selling them dearly in the United States; or they bought native-made products and exported them for profit to the rest of the world. Through this process they accumulated wealth, or capital, that they then reinvested in their businesses.

On the other hand, there were artisans, skilled craftsmen (including printers, blacksmiths, brick-layers, and carpenters) who produced many of the commodities necessary for early urban life. These artisans inhabited a world of tradition inherited from the guild systems of Europe. Rather than hiring employees, the master craftsmen took on apprentices who worked for a given period of years (usually six or seven), receiving room and board as recompense rather than a wage or salary. After the apprenticeship ended, workers became journeymen. After several years of wage labor, the journeymen, in turn, expected to become master craftsmen. Finally, there were unskilled laborers who worked for a wage. During this early republican period, craft workers created trade associations. Carpenters organized together, print-makers, and brick-layers. These early trade associations included masters, journeymen, and apprentices; and all three groups of skilled workers felt a unity of purpose, a community of art, and a common social bond. But these associations were not yet trade unions.

EMERGENCE OF TRADE UNIONS

Modern trade unions emerged only after the industrial revolution began to take shape. Because of New York's pivotal place as a trading center in the world economy, the merchant class began to accumulate capital. With their coffers enriched by the import-export trade, some of these merchants began to set up their own workshops to manufacture the goods usually made by skilled craftsmen. These workshops proved to be efficient and highly profitable. Thus, some of the wealthier artisans followed suit, transforming their own tradition-bound workshops into early modern versions of the manufacturing plant. While in the older craft workshops, the apprentice and the journeyman were bound to the master by traditional ties and communal associations, in these new proto-industrial workshops, the relationship between the master and the journeyman or apprentice was increasingly governed by a wage. The master hired the men he needed, paid them by the hour, and dismissed them if they were unnecessary. As masters became increasingly wealthy, the social and economic space between masters and journeymen likewise increased.

Soon the journeymen were organizing their own associations; and by the 1820s, journeymen associations began to strike against their masters for higher wages, better working conditions, and rudimentary social benefits. From these early journeymen associations, the modern trade union movement was born.

At the same time, as a direct result of these new economic forces, poverty increased, male laborers found their livelihoods increasingly precarious, and women began to enter the formal workforce. Excluded from the all-male craft associations, New York women worked in occupations generally associated with the household labor that they had done for centuries. They became street corner vendors, provisioners selling prepared foods, prostitutes, midwives, nurses, and seamstresses. As the workshop system advanced, and as technological change and new machines transformed textile labor, women textile laborers increasingly worked in early factories. In New York, in Baltimore, in Philadelphia, and in Massachusetts, women in various trades began organizing their own trade unions. And in 1825, New York seamstresses organized the first all-women's strike in the United States.

At first, these women trade unionists enjoyed considerable support from male wageworkers and male dominated trade unions. But that soon changed. Between 1834 and 1836, one of the first attempts to affiliate all trade unions within the borders of the United States took place with the conventions of the National Trades' Union (NTU). The NTU addressed the issue of women wage earners. While many of the conventions' delegates were labor radicals who advocated the abolition of the wage system and a rudimentary notion of economic democracy, these male trade unionists also objected to the “degradation” of women in factory work. Constructing a discourse based upon what one labor historian has called “a species of radical paternalism,” the NTU delegates sought to “protect” women from the ravages of capitalism. But that “protection” amounted to nothing less than an exclusion of women from union activity, except in a supporting or auxiliary role, as the wives, mothers, and daughters of good union men. The brief moment of inter-gender trade union cooperation ended and would not reappear in full force for another hundred years.

THE KNIGHTS OF LABOR

Despite early attempts at a national organization, such as the NTU, it was not until 1869 that laborers were able to come together in a truly effective national trade union, the Knights of Labor. During this period, employers and the state attempted to repress union organization through legal and extralegal means, including blacklisting, court injunctions, labor spies, and firings. Thus the Knights were originally a quasi-secret organization. But by the
1880s, with almost one million members, the Knights shed much of their secrecy and became one of the most influential labor organizations of the late nineteenth century. The Knights actively recruited women, African American, and Hispanic workers. They fought for and helped effect the abolition of child labor, the eight-hour workday, equal pay for equal work, women’s rights, and the Labor Day holiday. They advocated combining all craft associations into one big union that would protect the rights of all working people.

The power of the Knights of Labor ended in 1886, during the Haymarket Affair. After the Knights helped organize a general strike in Chicago, police fired into a large protest rally held by workers, killing four people. The next day, a group of anarchists held a rally in Haymarket Square protesting police actions. Someone—it is still unclear whether it was a police spy or an anarchist protester—threw a bomb into a group of police officers, killing eight. In turn, the police fired into the crowd of protesters, killing another eight and wounding more than one hundred others. In the following days, radicals, anarchists, and unionists were rounded up by state and local authorities; some were indicted and tried for conspiracy. The age of the Knights of Labor came to an end with one of the first “Red Scares” in American history. This was a pattern that would be repeated over and again for the next sixty years.

THE AFL AND THE IWW

As the twentieth century approached, the Knights of Labor left an ambiguous legacy for the American labor movement. On the one hand, their repression by the government led to the moderate craft unionism of the American Federation of Labor (AFL). On the other hand, the forms of radical solidarity promoted by the Knights found a new life in the syndicalism of the Industrial Workers of the World (IWW), known as Wobblies.

Samuel Gompers founded the American Federation of Labor in 1886 as a craft union federation that organized skilled workers. In other words, the AFL attempted to protect the privileges of a small segment of the American working class, often at the expense of less privileged, unskilled wage-workers. When the First World War began, the AFL issued a no-strike pledge, promising to keep industry working for the war effort. In return, the Woodrow Wilson administration began to actively support union organizing efforts. Between 1915 and 1920, union membership in the United States doubled. But the AFL’s increasing reliance upon governmental support further encouraged the moderate, responsible unionism that already distinguished this organization from the more radical efforts of the Knight of Labor.

In contrast, the Industrial Workers of the World (IWW), founded in 1905 by a group of radical activists and Socialist Party leaders, had a vision of unionization far different from the moderate program advanced by Gompers’s AFL. While the AFL sought to organize and protect the privileges of skilled craft workers, the Wobblies promoted the organization of all industrial workers, skilled and unskilled, into one big union. Further, the Wobblies were influenced by the European syndicalist tradition. A close cousin of anarchism, syndicalism was a set of political ideologies that sought to transform capitalism through direct action at the point of production. With slow-downs, work-to-rules actions, sabotage and strikes, syndicalists argued that workers themselves could challenge the control of industry by capitalists. And for the syndicalists in the IWW, unions that utilized these tactics were a means toward the broader end of social transformation. While the AFL sought to win higher wages and benefits for its members, the IWW attempted to overthrow capitalism itself. Although the IWW participated in or led important strikes in Lawrence, Massachusetts; Patterson, New Jersey; and throughout the lumber camps of the Northwest, it never had the influence or power of the American Federation of Labor. Because of its radical politics and unconventional tactics, the IWW was a target for constant surveillance and repression and was eventually destroyed by the forces arrayed against it.

But in the political environment of the early twentieth century, even the moderate AFL was a target of state-sanctioned repression. Because of government support, the AFL came out of the First World War stronger than ever before. And after the war ended, workers who had sacrificed much for the national effort sought some recompense for their troubles. During the summer of 1919 a strike wave washed across the United States, paralyzing industry on a national scale. Beginning just two years after the Bolshevik Revolution in Russia, what became known as the American Red Summer provoked profound fears among American capitalists and within the U.S. government. This Red Summer led directly into a new red scare. After his house was bombed, he claimed, by anarchists, U.S. Attorney General Alexander Palmer ordered the round-up and arrest of thousands of immigrant unionists. What followed was a series of legal and extralegal forms of political repression and in the years directly following 1919, there was a 30 percent drop in overall union membership.

THE CIO

The union movement went into retreat. But that changed after the stock market crash of 1929 and the beginning of the Great Depression. Because of its moderate, craft ori-
entation, the AFL proved incapable of taking advantage of the economic downturn to expand its base of support. A series of general strikes (in San Francisco, Toledo, and Minneapolis), a national textile strike, militant street actions, rent strikes, and general protests led the Roosevelt administration to enact the National Labor Relations Act (or Wagner Act) in 1935. This law gave legal support to labor’s right to organize and bargain collectively. Buoyed by new legislative openings, John L. Lewis, Philip Murray, Sidney Hillman, and other labor leaders already dissatisfied with the limits of the AFL’s craft unionism founded the Congress of Industrial Unions (CIO). Like the Knights of Labor and the IWW before it, the CIO set out to organize workers along industrial lines and had early success unionizing the steel and rubber industries. The early phase of this movement culminated in a 1936–1937 wave of sit-down strikes, beginning at the General Motors plant in Flint, Michigan. At the GM plant and elsewhere across the country, unionists sat down at their machines and occupied factory floors.

Following the sit-down wave, the CIO became increasingly close to the Roosevelt administration. When the United States entered the Second World War, the CIO offered a no-strike pledge in return for continued support from the government apparatus. While this no-strike pledge could not stop the many wartime wildcat work actions, it did have the effect of alienating the more militant and energetic local workers and leaders from the national CIO. If the government apparatus were to continue to support union efforts, the militancy of the early CIO had to be surrendered to the quest for industrial order. In place of class conflict, the CIO had to pursue a path of business-government-labor cooperation. This path, however, necessarily led to the decline of internal democracy, as unions increasingly became mechanisms for disciplining the shop floor. As one contemporary observer, C. Wright Mills, put it in his The New Men of Power, unions increasingly became “shock-absorbers” for both management and workers (p. 224).

After the war, workers and returning soldiers had confidence in their union strength and a sense of entitlement derived from having sacrificed so much for the national cause. This led to another postwar strike wave. In a now familiar pattern, this postwar strike wave was followed by a new red scare, political repression, and, most importantly for labor, the passage of the 1947 Taft-Hartley law. Taft-Hartley bureaucratized union grievance procedures, outlawed secondary boycotts, and required all union leaders to sign an oath that they were not Communists. This last provision forced the federation to expel many militant and radical organizers and to disaffiliate radical unions. Taft-Hartley made the militant actions that characterized the early days of the CIO extremely difficult.

THE IMPACT OF GLOBALIZATION

Despite this latest wave of government-sponsored repression, almost 35 percent of the American industrial workforce was unionized by mid-century. Because the new, moderate unionism of the CIO no longer differed in character from the AFL, the two unions affiliated in 1955. The AFL-CIO had considerable power between 1955 and 1973, making possible the formation of an American blue-collar middle class. Union workers bought houses, automobiles, and sent their children to college. And union prosperity benefited many American workers left out of direct unionization campaigns through pattern bargaining and by setting an ideal American standard of living that pressured non-union firms to provide better pay and benefits to their employees. But often, this American standard of living came at the expense of non-American workers. Now integrated into the government apparatus, the AFL-CIO supported American anticommunism around the world, working with the CIA to undermine radical unions in the Third World and helping to prop up right-wing dictators.

Beginning in the 1970s, new laws and new trade agreements that made capital increasingly mobile ushered in the age of globalization. In order to remain competitive with international firms, American companies increasingly sought out cheaper labor sources, moved production operations to the Third World, and, when they remained within the United States, demanded concessions and givebacks from their union workers. American unions were decimated, declining to the point that in 2007 approximately 8 percent of American workers were in a union. Although the AFL-CIO attempted to deal with this setback through a new emphasis upon organizing communities of previously unorganized workers in the service sector (janitors, hotel staff, and restaurant workers), its lack of success resulted in another split in the movement. Led by the Service Employees International Union (SEIU), a group of dissatisfied labor organizations formed a new federation, the Change To Win (CTW) coalition. Like the AFL-CIO, CTW promised a new emphasis upon organizing and militant action; and, most significantly, it has set out to organize Wal-Mart workers. To date, CTW has shown little progress in that direction, but its efforts continue.

At the same time, as American corporations increasingly outsourced production, they produced industrial zones in formerly underdeveloped nations. For instance, throughout the twentieth century RCA sought sources of cheaper labor. When its plant in Camden, New Jersey, organized, RCA opened a new production center in the non-union town of Bloomington, Indiana. When the Bloomington plant unionized, RCA opened a new manufacturing facility in the open-shop town of Memphis.
Tennessee. When the Memphis plant organized, RCA outsourced production to Ciudad Juarez, in Mexico. Soon afterward, the Juarez plant began organizing. In each case, as production relocated, unionization movements followed. In the early twenty-first century, many Third World countries became hotbeds of union activity. And in 2002, a former union leader, Luiz Ignatio “Lula” DeSilva, was elected president of one of the largest democracies in the Americas, Brazil. In these industrializing nations, union movements have successfully adopted tactics similar to those used by unions in the United States and Europe. But one important constraint on union activity remains. In these new industrial regions, unions have prospered under democratically elected governments. But authoritarian regimes continue to repress union activity through imprisonment, the murder and torture of union activists, and various other state-sanctioned methods. Consequently, the future of the international union movement may well hinge on the ability of activists and organizers to penetrate rapidly industrializing authoritarian countries such as China; and whether such a possibility exists under current political conditions is an open question.

UNIT ROOT AND COINTEGRATION REGRESSION
The study of the evolution through time of a variable or group of variables has existed since the dawn of empirical analysis in the mid-seventeenth century. The formulation of explicit statistical models for a time series process \{y_t\} is typically in the form of an autoregressive moving average model

\[
y_t - a_1 y_{t-1} - \ldots - a_p y_{t-p} = b + c_t + \theta_1 c_{t-1} + \ldots + \theta_q c_{t-q}
\]

where the innovation or shock \(c_t\) is assumed independently, identically distributed with mean zero and variance \(\sigma^2\).

When the roots of \(1 - \sum_{j=1}^{p} a_j z^j = 0\) lie outside the unit circle, the process \{y_t\} is stationary in the sense that \(y_t\) has a fixed mean and variance for all \(t\), and the covariance between any pair of values depends only on their distance apart in time, not on their absolute location. When the roots lie inside the unit circle, the process \{y_t\} is explosive in the sense that it quickly becomes unbounded as \(t\) increases. If there are \(d\) unit roots for the solution \(1 - \sum_{j=1}^{d} a_j z^j = 0\), and others are outside the unit circle, the process is called integrated of order \(d\), \(I(d)\), because the process can be interpreted as a \(d\)-fold partial sum of stationary process \(y_{d,t} = \sum_{j=1}^{d} y_{d-t,j}\), for \(d = 1, \ldots\), where \(y_{d-1,t} = (1 - L) y_{d,t}\), \(L\) denotes the backward shift operator, \(L y_t = y_{t-1}\) (Box and Jenkins 1970). When there is only one unit root \((d = 1)\), it is called an \(I(1)\) process or a unit root
process; thus when all the roots are outside the unit circle, it is also called an I(0) process.

Unit root process is intermediate between stationary and explosive process. Nelson and Plosser (1982) have found that many economic and financial time series are I(1) or I(2). There are many reasons that a time series of a variable is integrated. For instance, real business-cycle models predict that many real economic variables would contain a unit root. There is also the efficient market hypothesis in which the best predictor of tomorrow's price is today's price \( y_{t+1} = y_t + \varepsilon_t \) (Fama 1970).

When \( y_{t+1} = y_t + \varepsilon_t \), it is commonly referred to as a random walk process. Hall's consumption function theory (1978) implies that, under a simple version of the permanent income hypothesis, future changes in consumption are unpredictable, so consumption follows a random walk. The predictions of these theories often extend to multivariate relations. For example, if income has a unit root, then consumption as a function of income will also have a unit root. The residuals that can be viewed as a linear combination of consumption and income will not have a unit root. When some linear combination of I(d) variables has a lower order of integration, these variables are cointegrated, in Engle and Granger's terminology (1987).

UNIT ROOT PROCESS

If a variable, say \( y_t \), has a unit root, the shock to the variable never dies out. A unit root process can be written as the sum of past shocks plus an I(0) current shock. Because the sum of past shock is a dominant term in \( y_t \), this permanent component constitutes a stochastic trend. Information on the degree of persistence in a time series and, in particular, on its order of integration, can help to guide the construction or testing of economic theories.

Box and Jenkins (1970) proposed an informal data-analytic basis for the choice of \( d \). Formal testing of a unit root is usually conducted by fitting a \( p \)-th order autoregressive form

\[
y_t = \sum_{j=1}^{p} a_j y_{t-j} + \varepsilon_t
\]

or its error-correction representation,

\[
\Delta y_t = \rho y_{t-p} + \sum_{j=1}^{p-1} a_j \Delta y_{t-j} + \varepsilon_t
\]

where \( \delta = (1 - L) \), and \( a_0 = \sum_{i=1}^{j} a_i - 1 \). The null that \( \Sigma a_j = 1 \) is equivalent to the null \( \rho = 0 \).

Time series regressions that include integrated variables have statistical properties that are very different from the time series regressions with stationary variables. The least squares estimator of \( \rho \) when the regressor is I(1) converges to its true value 0 at the speed \( T^1/2 \), and has a limiting distribution that is a functional of Brownian motion (Chan and Wei 1988). Dickey and Fuller (1979) derive the \( t \)-statistics for the null hypothesis \( \rho = 0 \) by considering the limiting behavior of quadratic forms. The distribution of Dickey-Fuller \( t \)-statistic is tabulated by Dickey (1976).

Applying Dickey-Fuller procedure to the first difference of \( y_t \) provides a test of I(2) against I(1). When the process \( \{y_t\} \) may possess two or more unit roots, Dickey and Pantula (1987) recommend a “downward,” sequential \( t \)-test procedure starting with the greatest suspected number of unit roots, \( d \) (i.e., transform (2) into equivalent formulation (3) in terms of \( \delta^j y_t \)), because the “upward” testing procedure starting with a test for a single unit root is an inconsistent test. Pantula (1989) proves that the distribution of the relevant \( t \)-statistic under each null has the standard Dickey-Fuller (1979) distribution.

From the perspective of empirical work, (2) may be overly restrictive. The process \( \{y_t\} \) may also be a function of trend and serially correlated I(0) errors. Moreover, \( \{y_t\} \) may be subject to trend breaks or structural breaks with unknown breakdays, or trend may be misspecified (Perron 1989). The bulk of the large literature on tests for unit roots has been to propose tests that (1) are asymptotically similar under the general I(1) null, in the sense that the null distribution depends neither on the parameters of the trend process nor the parameters describing the short-run dynamics of \( \varepsilon_t \) (Phillips and Perron 1988); (2) have good power in large samples; and (3) exhibit small size distortions. Although the asymptotic size and power vary greatly across the proposed test statistics, the Monte Carlo findings for finite sample yield similar conclusions: The proposed tests have relatively low power against I(0) alternatives, and there are substantial size distortions for the tests. For instance, with 100 stationary observations, the one-sided 5 percent significance level Dickey-Fuller \( t \)-test has a power of only 0.19. On the other hand, processes that are I(1) but which have moderate negative autocorrelation in first difference are incorrectly rejected with high probability. (For detail, see Stock 1994).

COINTEGRATION REGRESSION

Multivariate time series methods are widely used by empirical economists. One important implication of economic theory is that certain ratios are stable. For instance, in response to growth in productivity and population, neoclassical growth models (King, Plosser, and Rebelo 1988) predict that output \( (y) \), consumption \( (c) \), and investment \( (i) \) will grow in a balanced way. That is, even though \( y_t, c_t, \) and \( i_t \) increase permanently in response to
increases in productivity and population, there are not permanent shifts in $c_t - y_t$ or $i_t - y_t$. In other words, these variables are cointegrated.

For ease of exposition, here we shall only focus on the classical analysis of $I(1)$ and $I(0)$ systems. Let $\{w_t\}$ be a sequence of $m \times 1$ vector of $I(1)$ time series observations. Vector autoregressive model (VAR) of the form

\[ w_t = \Pi_1 w_{t-1} + \cdots + \Pi_p w_{t-p} + v_t \]

(4) provides a flexible and tractable framework for analyzing $w_t$ (as in Hsiao 1979 and Sims 1980). Transforming (4) into an error-correction form provides a framework for analyzing both long-run and short-run economic relations

\[ \Delta w_t = \sum_{j=1}^{p-1} \Pi_j \Delta w_{t-1} + \Pi_p w_{t-p} + v_t \]

(5) where $\Pi_j = \sum_{i=1}^{j} \Pi_i$. $\Pi_m$ denotes the $m$-rowed identity matrix. If there are $m$ unit roots, $\Pi_m \equiv 0$, each series in the system is governed by a different stochastic trend. When there are fewer than $m$ unit roots in (4), say $n$, then rank $(\Pi_m) = r$, $r = m - n$, 1 $\leq n \leq m$. When rank $(\Pi_m) = r$, one can write $\Pi_m = \alpha \beta'$ where $\alpha$ and $\beta$ are $m \times r$ full column rank matrices. Since $w_t$ is $I(1)$, $\beta' w_{t-p}$ must be $I(0)$ to ensure compatibility between the left-hand and right-hand side of (5). Therefore, the matrix $\beta'$ is called the cointegrating matrix that describes “equilibrium” or “long-run” relations within a fully dynamic framework. The matrix $\alpha$ transmits the deviations from the long-run relations, $\epsilon_t = \beta' w_t$, into respective elements of $w_t$. The matrix $\Pi_j$, $j = 1, \ldots, p - 1$, describes the short-run adjustment pattern that provides information on how soon the “long-run equilibrium” is restored after any of the variables in the system are perturbed by a shock. In economics, the existence of long-run relations and the strength of attraction to such a state depends on the actions of a market or on government intervention. The concept of cointegration has been applied in a variety of economic models including the relationship between capital and output, real wages and labor productivity, and so on (King, Plosser, Stock, and Watson).

Several issues arise from the cointegration analysis. First, because $\beta' w_t$ is $I(0)$, $w_t$ must be driven by some common trends. In other words, cointegration signifies comovements among trending variables. However, only the rank of cointegration can be uniquely determined. The cointegrating matrix $\beta'$ is not uniquely defined. Any linear combination of cointegrating vector is a cointegrating vector or $\Pi_m = C^{-1} C \beta'$ for any $r \times r$ nonsingular constant matrix $C$. (Therefore, the maximum number of linearly independent cointegrating vectors in a system of $m I(1)$ variable, is ($m - 1$)). Normalization rule for the unique determination of the cointegrating matrix has to be used.

Second, although the least squares estimator with integrated regressor is consistent, it has very different statistical properties from the least squares estimator with stationary regressors (Chan and Wei 1988; Phillips and Durlauf 1986). Some of the estimated coefficients of (4) converge to the true values at speed $T^{1/2}$ and are asymptotically normally distributed; some converge to the true values at speed $T$ and have non-normal asymptotic distributions (Sims, Stock, and Watson 1990). This raises the issue of statistical inference because in some instances the usual test statistics can be approximated by chi-square distributions while in other circumstances, they cannot.

Third, to overcome the miscentering and skewness of the usual test statistics because of the issues of unit root distribution, one can either condition on the innovations driving the common stochastic trends of the system (Phillips 1991) or use the reduced rank regression technique (Johansen 1988; 1991). In a system of $m I(1)$ variables, the possible common trends vary between 1 and $m$. However, the knowledge of the rank of cointegration or nonstationarity (location of unit roots) is not generally known a priori. Johansen (1991) proposes likelihood-based tests for the rank of cointegration by considering the likelihood function of (5), whereas Stock and Watson (1988) propose a rank test for $\frac{1}{T^2} \sum_{i=1}^{T} w_i w_i'$ based on the fact that if there are $r$ linearly independent cointegrating relations, then $w_t$ are driven by $m - r$ common trends, hence the sum of cross-products of $w_t$ divided by $T^2$ can only have rank $m - r$. Unfortunately, neither method provides reliable inference in finite sample. Many Monte Carlo studies show that there are serious size and power distortions (Ho and Soresen 1996; Gonzalo and Pitarakis 1999).

The literature on unit root and cointegration analysis has greatly enhanced our understanding of dynamic econometric modeling of economic time series and provides a useful repertoire of tools for empirical analysis. However, unit root tests and cointegration analysis also raise serious finite sample issues. Tests with better finite sample size and power remain to be developed. More attention to economic theory and integrating economic analysis with time series analysis could also be fruitful.

**UNITED ARAB REPUBLIC**

The United Arab Republic (UAR) was founded in 1958 as a political union between Syria and Egypt. The union reflected a sense of Arab nationalism and solidarity (Pan-Arabism). It was largely driven by a desire to overcome dividing borders viewed by many as an artificial creation of European colonial powers. However, the union eventually collapsed in 1961 due to widespread sentiments in Syria that it had become a vehicle for furthering Egyptian hegemony.

**PAN-ARBISM**

A major driving force behind the formation of the UAR was Pan-Arabism. Sentiments of collective Arab nationalism had already emerged in the Middle East in the early twentieth century. These attitudes were largely motivated by a desire to shake off the corrupt, inefficient, and alien rule of the Ottoman Empire. Shared experience coupled with a common language and culture engendered collec-
itive sentiments that spread throughout the Arab-speaking Middle East.

After conquering the Middle East during World War I (1914–1918), the colonial powers divided the Arabs by drawing previously nonexistent political frontiers. Among other things, segmentation enabled the victorious Europeans to reward friendly Arab leaders with a state that they could govern. Thus, local leaders, whose support for the Europeans during the war was initially driven by encompassing Arabism and the desire to rid themselves of the foreign Ottoman rule, now had an incentive to continue cooperating with the Europeans and encourage loyalties to the smaller, newly created states. In almost every Arab country, schemes for regional Arab unity were countenanced with efforts to instill a sense of patriotic solidarity and identification with the new state through the creation of a national flag, an anthem, and other local symbols. Nonetheless, modern technology, mobility, and newspapers and other printed materials enhanced the sense of collective Arabism that transcended the new political boundaries. Furthermore, the new regimes found that by appealing to sentiments of Arabism, they could increase local support and further their legitimacy.

Attempts to balance the tension-laden tendencies of Pan-Arabism and local regime interests continued to shape Arab politics and society well into the decades that followed. The foundation of the UAR and its demise were a product of such dynamics.

PRINCIPLE ACTORS OF THE UNION

The principle actors behind the union were the Ba'thists and Nasserites in Syria and President Gamal Abdel Nasser (1918–1970) of Egypt. When Syria became a democracy in 1954, mass public support for a new, all-encompassing Arab state got reflected in the platforms of rival political parties. Both the Communists and the Muslim Brotherhood supported transcending frontiers, although the Communists preferred closer ties with the Soviet Union. The growing merchant class in Syria saw economic opportunities in the abolition of borders and, thus, also viewed a union favorably. These domestic dynamics led the powerful Syrian Ba’th Party, headed by Michel ‘Aflaq (1910–1989) and Akram Hourani (1912–1996), to propose the idea of a united republic with Egypt. In particular, the Ba’thists, espousing an ideological platform that combined Arab nationalism, socialism, and secularism, found itself in domestic struggles for power against the strengthening Communists. The party hoped that the union would lead to the collapse of its competitors.

In Egypt, meanwhile, the “Officers’ Coup” in 1952 saw Colonel Nasser seize power from King Farouk (1920–1965) and emerge as the new Egyptian president. Nasser’s firm stance against the British presence in the Suez and the nationalization of foreign property had made him an admired leader throughout the Arab world. After surviving the Anglo-French and Israeli invasion of 1956, Nasser was depicted as a great, modern-day Arab hero capable of defending the interests of the Arab world against the imperialist powers. His popularity made him an agreed-upon candidate for leading the union, although Nasser himself was initially reluctant to merge the two countries. He feared problems associated with merging the two very different economic systems and with unifying the civil and military institutions. The Ba’thists in Syria, on the other hand, were optimistic. They believed Nasser would entrust them with the governance of Syria. Ultimately, they managed to convince him of the feasibility of the union.

THE RISE AND DEMISE OF THE UNION

In February 1958 President Nasser of Egypt and President Shukri al-Kuwatli (1891–1967) of Syria signed the unification treaty. Following a referendum held simultaneously in both countries, the two countries were integrated and the UAR was born with a new federal constitution, with Cairo as its capital, and with Nasser as its president. Separate Egyptian and Syrian citizenship was abolished. The UAR adopted the Egyptian flag with an addition of two stars to represent the two members of the union. The birth of the union was greeted with such enthusiasm throughout the Middle East that it was followed by a series of attempts by pan-Arabists elsewhere to overthrow regimes perceived as pro-Western. Indeed, following a coup d’état in 1958, Iraq declared its intent to join the UAR. That same year, the United Arab States, a loose federation of the UAR and Yemen, was also established.

Although the union was initially received with immense enthusiasm in both of the UAR’s member countries, disillusionment soon took over popular attitudes in Syria. The disparity of power between Egypt and Syria made the former the undisputable hegemonic force, despite the formal federal structure of the new republic. The authority bestowed on the president made Nasser extraordinarily powerful and allowed him to impose unpopular economic and social policies in Syria. Even though the Ba’thist Hourani was named one of four vice presidents, he was practically powerless and resigned in protest as early as December 1959. Egypt’s political superiority left very little room for Syrian input in administering the affairs of the union. Leading figures from the Syrian regime, particularly the military, were transferred to Cairo. This way, Nasser could ensure they were isolated...
from their power bases. Officials and military personnel from Egypt were reassigned to Syria, where they in practice took control of the Syrian bureaucracy and security forces.

In addition, the Ba’th Party dissolved itself in compliance with the ban on all political parties other than Nasser’s Arab Socialist Union, a condition that Nasser presented before consenting to the merger and which the Ba’thists accepted under the misguided assumption that Syria would preserve a degree of autonomy in the new institutional framework. The Communists and the Muslim Brotherhood, meanwhile, were brutally repressed as the Egyptians increasingly asserted their authority. Similarly, the Syrian press was seized by the new regime. Furthermore, attempts to impose Egypt’s socialist policies in Syria left the Syrian merchant class not only without access to Egyptian markets but also facing stiff limitations on its ability to maneuver within the Syrian part of the UAR. Likewise, land reforms made large landowners unhappy. In short, Syrians of all political and social streams were left disenchanted and feeling as though they were ruled by outsiders.

A 1961 coup d’état in Syria led to its withdrawal from the union and a renewed assertion of its independence. A short time later, the United Arab States was abolished following Yemenite criticism of Nasser’s heavily socialist policies. Witnessing the Syrian experience, the Iraqi regime too decided to stay out of the union, despite its initial vow of commitment to join. Egypt retained the name of UAR until 1971.

Following yet another coup d’état in 1963 in Syria, unity talks were again undertaken, but without results. The failure of the UAR left many leaders in Syria and the rest of the Arab world determined never to allow their country to be pushed into such a subordinate position. Thus, despite continuing widespread sentiments of Arabism, the demise of the UAR brought about an end to any real chance of integrating Arab countries into a single state. And by the end of the 1980s, notions of pan-Arab unity had all but disappeared.

UNITED NATIONS

The United Nations (UN) is a global organization of states that aims to find cooperative solutions for international security, economic, and social problems. The first formal use of the term United Nations appeared in the Declaration by the United Nations (January 1, 1942), in which twenty-six Allied countries pledged to defeat the Axis Powers and subscribed to the principles of the Atlantic Charter (August 14, 1941) during World War II (1939–1945). These principles included “the establishment of a wider and permanent system of general security.”

From August to October 1944, delegates from the United States, the Soviet Union, the United Kingdom, and the Republic of China met at the Dumbarton Oaks estate in Washington, D.C., to negotiate the formation of a new organization to replace the League of Nations. Most of the outstanding issues were settled at the Yalta Conference (February 4–11, 1945) among the leaders of the “Big Three” nations: U.S. president Franklin D. Roosevelt (1882–1945), British prime minister Winston Churchill (1874–1965), and Soviet general secretary Joseph Stalin (1879–1953). Shortly thereafter, delegates of fifty nations met in San Francisco to finalize the negotiations, culminating in the signing of the UN Charter on June 26, 1945. On August 8, 1945, the United States became the first country to ratify the Charter. The United Nations Organization came into being on October 24 (celebrated since 1948 as United Nations Day) when the majority of original signers, including the great powers (the four Dumbarton Oaks conveners and France), had ratified the Charter.

STRUCTURE

Although the UN Charter opens with the famous phrase “We the peoples of the United Nations,” the United Nations is primarily an organization of sovereign states. Membership is open to all “peace-loving states” (Article 4), but disputes over the admission of new members fell victim after World War II to the cold war conflict. In 1955 the United States and the Soviet Union reached a compromise that allowed for the admission of sixteen new members. Still, controversy persisted over the membership status of the partitioned states of Germany, Korea,

The UN Charter also established the six “principal organs” of the United Nations: the General Assembly, the Security Council, the Economic and Social Council, the Trusteeship Council, the International Court of Justice, and the Secretariat. The General Assembly is the United Nations’ plenary body. Aside from occasional special sessions, it meets in annual sessions that usually start in September and last for three months. The General Assembly oversees subsidiary bodies, calls international conferences, approves the budget, and adopts nonbinding resolutions on a wide variety of issues. General Assembly decisions are taken by majority vote based on a one-state–one-vote principle. Since 1987, after lobbying by the United States, critical votes on the budget are taken by unanimity rule (instead of the historical two-thirds majority) in an effort to curtail large annual budget increases. Budget assessments are made on a capacity-to-pay basis. As of 2005, the United States was responsible for 24 percent of the UN budget, followed by Japan (19 percent) and Germany (8 percent). Countries do not always meet their budget obligations in a timely manner: In September 2005 member states owed the United Nations $3 billion in outstanding peacekeeping and regular budget payments ($1.2 billion from the United States alone).

The Security Council has primary responsibility for the maintenance of international peace and security. Under chapter VII of the UN Charter, the Security Council can adopt coercive measures, including economic sanctions and the use of force, which are binding on individual member states. The Security Council has five permanent members (China, France, the Russian Federation, the United Kingdom, and the United States) and ten nonpermanent members that are elected for two-year, nonrenewable terms by the General Assembly. (Until 1965, the Security Council only had six nonpermanent members.) Security Council resolutions require an affirmative vote of nine members, including the five permanent members. By 2005 the permanent members had exercised their veto right 244 times, but on only twenty occasions since 1990. The veto threat is, however, still a powerful tool to block unwanted resolutions.

The Economic and Social Council coordinates and supervises the work of numerous commissions and expert bodies on economic and social matters, including human rights. Members are elected for three-year terms by the General Assembly. The Economic and Social Council’s membership has gradually expanded from eighteen to fifty-four. The Economic and Social Council has limited powers other than its ability to submit recommendations to the General Assembly (by majority vote). Formally, the Economic and Social Council coordinates the activities of various specialized agencies, including the World Bank Group and the International Monetary Fund (IMF). Developing countries have long, and unsuccessfully, pushed for a greater role for the Economic and Social Council vis-à-vis these organizations. Other specialized UN agencies, each with its own budget, membership, and charter, include the International Labor Organization (ILO), the Food and Agriculture Organization (FAO), the United Nations Educational, Scientific, and Cultural Organization (UNESCO), and the World Health Organization (WHO).

The Trusteeship Council was set up to monitor UN trust territories that were not designated as strategic by their administering powers (strategic trust areas were the Security Council’s responsibility). The Trusteeship Council ceased its operations on November 1, 1994, when the last remaining trust territory (Palau) became independent.

The International Court of Justice, located in The Hague, Netherlands, issues advisory opinions on legal questions brought to it by other UN organs and settles legal disputes submitted to it by member states. Its fifteen judges are elected for nine-year terms by the General Assembly and Security Council. By 2005 the International Court of Justice had delivered twenty-five advisory opinions and eighty-seven judgments on contentious cases, primarily on border and maritime disputes. The binding nature of International Court of Justice opinions depends on whether state parties have previously agreed to its compulsory jurisdiction.

The Secretariat is the United Nations’ bureaucracy. In 2005 it employed around nine thousand international civil servants who answer to the United Nations alone for their activities. While most civil servants are stationed at the UN headquarters in New York, the United Nations also maintains staffed offices elsewhere. The Secretariat is headed by the secretary-general, a prestigious post that has been occupied by Trygve Lie (Norway, 1946–1952), Dag Hammarskjöld (Sweden, 1953–1961), U Thant (Burma [Myanmar], 1961–1971), Kurt Waldheim (Austria, 1972–1981), Javier Pérez de Cuéllar (Peru, 1982–1991), Boutros Boutros-Ghali (Egypt, 1992–1996), Kofi Annan (Ghana, 1997–2006), and Ban Ki-moon (South Korea) who was sworn in on December 14, 2006, and began serving on January 1, 2007. Critics have charged that the demands of being the world’s primary diplomat sometimes undermine the secretary-general’s ability to also be an effective manager of a large bureaucracy.
PEACE AND SECURITY

When states sign the UN Charter, they agree not to use or threaten force “against the territorial integrity or political independence of any state, or in any manner inconsistent with the Purposes of the United Nations” (Article 2). There are two circumstances under which force is consistent with the United Nations’ purposes: when it is exercised in self-defense (Article 51) and when the Security Council approves a collective action under chapter VII. The first important authorization of a collective action occurred in 1950 (July 7), when the Security Council authorized the United States to install a central command under the UN flag to restore peace and security following the armed attack by the Democratic People’s Republic of Korea (North Korea) against the Republic of Korea (South Korea).

UN action in Korea was possible only because the Soviet Union had temporarily vacated its Security Council seat in protest against nationalist China’s representation. After the Soviet delegate returned, the General Assembly adopted the “Uniting for Peace” resolution, which allowed the General Assembly to circumvent a deadlocked Security Council through special emergency sessions. This procedure has been invoked ten times, most notably in 1956 to order the French and British to end their military intervention in the Suez Canal and to create the UN Emergency Force (UNEF I) to provide a buffer between Egyptian and Israeli forces.

UNEF I was the first large-scale example of peacekeeping, an activity not mentioned in the Charter. During the cold war, peacekeeping missions were generally limited to providing a buffer between warring parties at the invitation of those parties, prime examples being the long-standing UN forces in Cyprus and Lebanon. An exception was the more ambitious 20,000-person force employed in the Congo between 1960 and 1964. This operation failed to achieve its main objectives, led to a protracted conflict about peacekeeping financing, and cost respected Secretary-General Hammarskjold his life when his plane crashed in the Congo on September 18, 1961.

UN activity in international security was reinvigorated with the end of the cold war. In 1988 and 1989, for the first time in a decade, the Security Council authorized new peacekeeping missions that were sent to cold war hotspots such as Afghanistan, Angola, Namibia, and Nicaragua. A transformation in UN collective security occurred with the adoption of Security Council Resolution 678 on November 29, 1990, which authorized the use of “all necessary means” if Iraq would not vacate Kuwait by January 15, 1991. The resolution conferred legitimacy on the use of force against Iraq by a U.S.-led coalition. Since then, the Security Council has granted similar authorizations to (groups of) states in eleven cases, including East Timor (with Australia as the leading state) and Haiti (with the United States as leader).

A second significant shift occurred in 1992, when the Security Council authorized the deployment of large peacekeeping forces to end civil wars in Cambodia and Yugoslavia. This was merely the prelude to increased UN involvement in domestic conflicts across the globe. Between 1991 and 2005, the Security Council authorized forty-eight peacekeeping and other multinational uses of force, almost all concerning civil conflicts rather than interstate wars. These efforts were not without risk: more than two thousand UN peacekeepers have lost their lives, most since 1991. The United Nations has also become actively involved in postwar reconstruction and has even run transitional administrations, most notably in East Timor and Kosovo. Moreover, it has created international tribunals to try war crimes in Rwanda, Sierra Leone, and the former Yugoslavia.

Despite its active record since the cold war’s end, the United Nations’ contribution to the preservation of peace and security has come under serious scrutiny. First, the United Nations has been unable to prevent genocides in Rwanda (1994) and the Sudan (2005). Second, the Security Council has been deadlock on important cases and has not been able to prevent states or coalitions of states from going it alone in the absence of UN authorization, as illustrated by the intervention of the North Atlantic Treaty Organization (NATO) in Kosovo in 1999 and the U.S.-led invasion of Iraq in 2003. Third, weak and understaffed UN missions have occasionally done more harm than good, as illustrated by the United Nations’ failure to maintain the promised safe haven of Srebrenica (1995). Fourth, UN-imposed sanctions on Iraq caused much suffering among the Iraqi population while failing to resolve the conflict. Moreover, the UN “Oil for Food” office allowed massive fraud to occur in the administration of the sanctions.

Some critics justifiably lament UN bureaucratic and peacekeeping practices, as acknowledged by the United Nations’ remarkable Brahimi Report (2000). Yet, the United Nations ultimately remains an organization of states. The United Nations can be a useful vehicle for cooperation on those issues where states are committed, but it has few means beyond persuasion to compel states to make committed efforts. In all, most analysts believe that the United Nations has had a modest but significant positive impact, especially on the resolution of civil wars.

OTHER ISSUES

The United Nations has played an active role on a large range of other issues. The United Nations was an important arena for the transformation of former colonies into sovereign states. To many new states, UN membership
served as the affirmation of their sovereignty. Moreover, General Assembly Resolution 1514 (December 14, 1960) became the most influential political declaration of the existence of a right to self-determination and the illegitimacy of colonial rule.

The 1948 Universal Declaration of Human Rights provides the foundation for the treatment of human rights in the United Nations. The United Nations administers other global human-rights instruments, such as the Convention Against Torture and Other Cruel, Inhuman, or Degrading Treatment or Punishment (1987), and organizes global conferences, such as the Beijing Women’s Conference (1995), that set the normative debate on human rights. It has, however, few enforcement mechanisms other than public shaming through the Human Rights Commission, which critics charge is political and selective.

The United Nations has also provided a forum for arms control negotiations and administers important disarmament treaties. An independent agency, the International Atomic Energy Agency (IAEA), monitors observance of nuclear treaties and can refer violators to the Security Council, which can then decide on coercive measures.

The United Nations also plays an important role in economic development and humanitarian relief, primarily through special programs and funds, such as the UN Children’s Fund (UNICEF), the UN Development program (UNDP), and the Office of the UN High Commissioner for Refugees (UNHCR). UNHCR provides a crucial coordinating role in providing relief to the world’s refugees (around twenty million in 2005). UNDP is most active in the development and monitoring of the UN Millennium Development goals: an ambitious set of development targets to be achieved by 2015.

The most difficult issue for the United Nations continues to be the Middle East. The United Nations was instrumental in creating the state of Israel and in resolving the 1956 Suez crisis. Yet, its ability to play a constructive role has been compromised by increased politicization. Israel and its defenders charge that the United Nations regularly adopts inflammatory resolutions that unfairly target Israel. For example, between 1975 and 1991, the General Assembly annually adopted a resolution that equated Zionism with racism, a charge that resurfaced at the World Conference Against Racism, Racial Discrimination, Xenophobia, and Related Intolerance, held in Durban, South Africa, in 2001. Defenders of Palestine contend that Israel has repeatedly ignored General Assembly and Security Council resolutions, as well as International Court of Justice rulings.

Reform is also perennially on the United Nations’ agenda. Reform attempts generally involve the creation of a blue-ribbon committee, including the High-Level Panel on Threats, Challenges, and Change, established in 2003. The recommendations of these committees rarely lead to fundamental changes. Instead, the United Nations regularly reinvents itself in response to major events and the ensuing new demands on the organization.

UNIVERSALISM

Universalism is the proposition that there exist single objective standards, independent of culture, by which moral and epistemological questions are each correctly judged. Broad universalism includes any concept or doctrine that applies to the totality of the relevant set, such as human beings. Some religions have doctrines that are believed to apply to all humanity.

Moral universalism posits a unique ethic that applies to all human beings and is comprehensive for all human action, including action that affects nonhumans. Because the universal ethic is independent of culture, it cannot derive from the beliefs of any culture or any generalization from practices and actions. A universal moral standard can be derived only from premises that apply to all human beings, such as human nature. Moral universalism is implied in the concept of human rights and such documents as the United Nations 1948 Universal Declaration of Human Rights.

The concept of a universal ethic or “natural moral law” in European philosophy was developed by the ancient Greek Platonists and Stoics. German philosopher Immanuel Kant based his moral philosophy on the concept that rules can be universalized. Utilitarian moral philosophy, based on what is best for society, is also intended to apply universally. Universalism is also present in the philosophy of natural rights and associated with natural moral law as a standard for judging legislation.

Philosopher John Locke described natural moral law in his work on political philosophy, Two Treatises of Government ([1690] 1947). In the Second Treatise, Locke states as his premise for the “law of nature,” or natural law, that human beings are all equal and independent.

Human beings are biologically independent, for feeling and thinking and choosing take place individually. Equality means that the capacity for reason and choice is common to the human species and that there is no biological basis for one set of humans to be regarded as superior to others. Nihilists, relativists, and supremacists deny the equality premise, while those with a holistic philosophy dispute the independence premise.

Locke’s “law of nature” prescribes that it is morally evil to harm others in their lives, health, liberty, or possessions. The existence of such a universal ethic can be claimed by setting criteria for the ethic and then arguing that if a derived ethic fits the criteria, then it exists, just as we can set criteria for the existence of airplanes, and then if a machine fits the criteria, we must conclude that airplanes exist. The criteria could be the following four propositions:

1. The ethic is universal to all humanity.
2. The ethic is comprehensive, applying to all human action.
3. The ethic is logically consistent.
4. The ethic is not arbitrary, not merely based on the whims or beliefs of one or more persons.

Another strand of natural moral law is based on the ethical philosophy of Aristotle, which has been revised by libertarian scholars such as Murray Rothbard and by Objectivist philosophers starting with Ayn Rand. They posit some natural end inherent in human nature such that actions that are inconsistent with this end are immoral. Other philosophers, such as Jürgen Habermas, base universalist concepts on communicative action or a dialectical process, through which a consensus can be achieved by dialogue.

Epistemological universalism posits the existence of objective knowledge that human beings are able to learn. Objectivists and realists in epistemology claim that human beings have the cognitive ability to observe and explain the universe as it actually is rather than merely forming subjective interpretive beliefs. In contrast, hermeneutics, relativists, and particularists such as Michel Foucault claim that human minds have bounded cognition, not just making errors but necessarily interpreting observations using prior beliefs, making absolute objectivity impossible. Some philosophers seek a middle ground between relativism and objectivism, such as the belief that human beings can achieve knowledge but that it is not certain or comprehensive. Universalists can argue that the proposition that there are no universals is itself either universal or not; if so, the proposition is self-contradictory, and if not, it has no general impact.

Universalists have explained the human capacity to obtain objective knowledge from evolution, which selected for beings whose survival depends on beliefs consistent with their environmental reality. Knowledge can come from a priori insights such as the concept of cause and effect, and from the capacity to reason, using logic and evidence from observation. Most scientists evidently believe in epistemological universalism, in being able to discover theories that explain reality.

Economics, for example, presumes premises that apply universally to all humanity. Economic axioms include diminishing marginal utility, economizing to maximize benefits or minimize costs, and the physical
constraint of scarce resources. If economics as a social science is founded on these premises, then it must be possible to know these premises and their implications, and such knowledge must consist of shared beliefs that can be learned. Moral universalism is connected to epistemological universalism in that if human beings can know science, there is no reason to exclude moral philosophy from what can be objectively known.

Subjectivism and objectivism are not necessarily opposites in moral philosophy. In economics, we can posit that the values placed on goods are purely subjective, based on individual interests. Yet these values result in bids and offers in a market, which create objective prices and, together with other premises such as scarcity, form the basis of an objective theory of prices. Likewise in ethics, we can accept that each person has subjective values about human action and situations but that these values form the basis of an objective ethic if we also have premises such as that all human beings have an equal moral worth or that their values have an equal moral standing.

UNIVERSITY OF OXFORD

In company with the other twelfth-century universities of Paris and Bologna, Oxford can claim to be among the oldest of the European universities. Its foundation date, often a matter of fantastic speculation, remains unclear. All that can be said is that Oxford recognizably became a university between 1192 and 1200. Located in a river valley fed by tributaries of the Thames River, the town and the university were named for the river crossing (oxen-ford). Since no new university was established in England (although four or five in Scotland) until the formation of the University of London in the 1820s, Oxford and Cambridge (collectively termed Oxbridge or less frequently Camford) long held a duopoly on the education and training of leading politicians, Roman Catholic and afterward Church of England clergy and bishops, civil service administrators at home and abroad, and representatives of the arts and sciences. Even the Scots, with their own fine university traditions, attended the ancient universities in order to take advantage of their connections and networks.

Oxford in the twenty-first century remains one of a handful of world universities correctly described as collegiate. It is a federation of some seven permanent private halls and thirty-nine self-governing and endowed colleges scattered about the city of Oxford. A good number of these are twentieth-century foundations, updating ancient traditions to take advantage of new subjects and new kinds of students. The first colleges appeared in the thirteenth century, but most were founded later. Historically associated with teaching and student residence, the first college to actually admit undergraduates was New College in the fourteenth century. Women's colleges date from the 1860s. Infamously, however, women did not receive degrees until 1920 (or 1948 at Cambridge). Only Saint Hilda's College, founded in 1893, is restricted to women.

Responsibility for teaching and scholarship is divided between colleges and the university, between tutors (called dons from the Latin *dominum* or master) and professors, but from the sixteenth century (the early modern period) until recently the colleges were dominant. That was mainly, if not entirely, a consequence of the Protestant Reformation, expanded royal government, and international trade and rivalry. Loyal and well-educated administrators were required for service in church and state. The small size of the colleges and their systems of personal instruction and discipline in a residential setting were well suited for the education of potential leaders. The new elites were heavily drawn from established families. The collegiate university primarily bestowed its blessings on those already favored; in particular, the scions of landed society influenced the tone of the university by their often careless but also glamorous habits well into the nineteenth century.

In recent decades, considerable scholarly attention has been directed to the social composition of Oxford through the ages, a reflection of current concerns about access to higher education. However, owing to the absence
of university matriculation records, estimates of the social composition of Oxford are harder to provide for the period before 1565. Entries afterward are listed by hierarchical status rankings, rather than by social or occupational groupings, as is present practice, and historians disagree on how to interpret them. The earlier records kept by colleges are often incomplete or confusing.

In the broadest terms, it can be said that until very recently wealth and privilege were always accorded a warm reception at Oxford. The numbers of recruits from the poorer sections of English society, meaning the children of farm laborers in the earliest centuries or industrial workers in the later ones, were generally in short supply. To give an example from Lincoln College from 1680 to 1799, of 972 admits, over half came from landed or gentlemanly families and another 266 from clergy, to include the higher ranks. Only 155 were listed as plebeian, a catchall category difficult to refine. A more complete analysis of the entire university for the 1901–1975 period, comprising 3,512 entries, more clearly indicates the changes. Professional families accounted for 1,564 admits; 1,059 were from commerce, finance, and industry, and 217 from white-collar families. Only 182 can be called skilled workers, and only several dozen fit the description of unskilled or manual workers.

As a generalization, it can be ventured that Oxford’s social transformation from a university serving mainly the sons of landed and clerical families began to shift from about 1850, when professional and business families started to become dominant. This was the pattern that could be expected of most elite institutions. Gradually but firmly Oxford ceased to be a university of the traditionally privileged and became instead the destination of new generations of outstanding undergraduates from middle-income families, befitting the economic transformations that had occurred as a result of industrialism and the expansion of the urban professions.

As a center of learning and scholarship, Oxford’s reputation declined in the Age of the Enlightenment. Enrollments fell, teaching was neglected, and one famous undergraduate, the future historian Edward Gibbon (1737–1794), characterized the dons of his day as addicted to “port and prejudice.” More recently, historians have uncovered evidence for greater intellectual vitality than previously supposed. Yet it is the case that a serious and almost total educational transformation of the university and its colleges did not occur until the next century. The first step around 1800 was a demanding and subsequently famous honors examination in the subject of literati humaniores (called “Greats”). Composed of classical languages, philosophy, and history, it became the prototype of later competitive examinations. For a long while, “Greats” was regarded as the leading subject, attracting the best and most success-minded students. To begin with, improvements in teaching and examining were internal reforms, but criticisms persisted that the university and its colleges tolerated weak students, gave scholarships to the unworthy, failed to impose needed discipline, were slow in furthering the advance of modern and scientific subjects, and misused plentiful endowments. Oligopoly control of the colleges and central administration was attacked. By the middle of the nineteenth century, public opinion demanded radical reforms. For some twenty years thereafter, royal and other commissions recommended, and Parliament introduced, changes affecting all aspects of governance, financing, and the curriculum. Research was added to teaching as an academic mission, and professorial chairs were created in new subjects. If Cambridge led the way in the mathematical sciences, Oxford excelled in classical languages, ethical philosophy, and medieval history. At present, Oxford is well represented in all fields of intellectual inquiry.

Repeal of two inherited restrictions in the Victorian period furthered the process of renewal and scholarly excellence. Celibacy was abolished as a condition of holding college teaching appointments, a major step in the formation of professional academic careers; and non-Anglican undergraduates were admitted without being required to take an oath of allegiance to the Thirty-Nine Articles of the Church of England. Since half the kingdom adhered to other denominations, the pool of worthy candidates widened. However, a certain element of snobbery persisted well into the Edwardian period, not only toward the few working-class undergraduates in attendance but also toward students of Jewish origin or from India and Africa.

In the nineteenth and twentieth centuries, Oxford was also renowned as the training ground of proconsuls, the distinguished imperial administrators in the heyday of the British Empire. Under Benjamin Jowett (1817–1893), its legendary master, Victorian Balliol College acquired a reputation as the nursery of prime ministers, but the great William Gladstone (1809–1898), who became prime minister in 1868, had studied at Christ Church, the most aristocratic of the colleges, although he was not descended from landed gentlemen.

Protesting a growing secularism and religious tolerance, John Henry Newman (1801–1890), a fellow of Oriel College, left Oxford in 1842 and converted to Roman Catholicism. His subsequent reflections and lectures, published under the heading of The Idea of a University (1853), became among the most influential and lasting books ever written on the purpose of a liberal education. But Newman was right. Oxford had indeed changed. Once described as the “home of lost causes,” a reference to the university’s sometime attachments to
deposed monarchs and High Church principles, or, romantically, as a place of “dreaming spires,” an allusion to its distance from social realities, Oxford was once again at the center of the transformed educational and intellectual life of a modern Britain. Oxford dons helped establish new universities, such as Bristol, and fully participated in outreach or extension movements. Rhodes Scholarships, a bequest by the imperialist Cecil Rhodes (1853–1902) at the turn of the twentieth century, brought overseas students to the university, as did the introduction of advanced research degrees. Oxford’s influence spread throughout the English-speaking world, indeed, everywhere.

The list of distinguished men and women who studied or taught at Oxford is endless. In the fourteenth century, William of Ockham (c. 1285–1349) added to the luster of the university’s fame in logic. In the same century, John Wycliffe (c. 1330–1384), master of Balliol, challenged the papacy by advocating a Bible in the vernacular. The seminal philosopher John Locke (1632–1704) was at Oxford in the late seventeenth century. In the following century, Edmund Halley (1656–1742) gave his name to a comet, and starting in 1729 John Wesley (1703–1791) and Charles Wesley (1707–1788) initiated practices that resulted in the birth of Methodism. Romantic poets like Percy B. Shelley (1792–1822, expelled for atheism) and Matthew Arnold (1822–1888) were at Oxford in the nineteenth century. Two celebrated twentieth-century graduates were Lord Curzon (1859–1925), viceroy of India and chancellor of the university, and Vera Brittain (1893–1970), who studied at Somerville College (founded in 1879) and became a leader of the women’s emancipation movement. Closer to the present, A. H. Halsey put two celebrated twentieth-century graduates were Lord Curzon (1859–1925), viceroy of India and chancellor of the university, and Vera Brittain (1893–1970), who studied at Somerville College (founded in 1879) and became a leader of the women’s emancipation movement. Closer to the present, A. H. Halsey put the political philosopher Isaiah Berlin (1909–1997) was one of the most respected and admired Oxford personalities of the twentieth century.

The British Isles (to include Ulster) currently possess well over a hundred institutions denominated universities and numerous polytechnics, specialized schools, and further education colleges. Yet despite competition, Oxford’s superior reputation remains. Its long history, endowments, magnificent libraries and collections of art, exquisite gardens, splendid architecture, and distinguished graduates at home and abroad provide advantages that guarantee its continued presence among the top five or ten research universities in the world as measured by peer approval.

In the twenty-first century Oxford recruits more broadly than ever before. The collegiate system is intact but less dominant. High technology, laboratory science, medicine, and postgraduate research are more closely associated with the professors than with the tutors, and with the university more than with the colleges. New market-based initiatives for financing have enhanced the importance of the central administration. However, as the bulk of Oxford’s income is derived from the government, institutional independence and academic freedom are serious issues for the twenty-first century. Universities everywhere are being called upon to address multiple social problems, generate wealth, and improve national efficiency in a global environment. However challenging these conditions, it is abundantly clear that contemporary Oxford has little interest in becoming a home for lost causes.

UNIVERSITY OF TEXAS INEQUALITY PROJECT

A new body of empirical literature on economic inequality emerged in the early- and mid-1990s that sought to establish cross-country and timewise analysis of the relationship between economic growth, income levels, and income distribution. At a fundamental level, this literature was concerned with exploring questions posed by Simon Kuznets in the mid-1950s about the relationship between income and inequality levels. His hypothesis was that if one were to plot inequality levels against income levels over the long run, this relationship could be described by an inverted U curve. As countries grew from an agricultural to an industrial economy, inequality would go up
initially, with few people working in the high-productivity and high-income industrial sector. As more and more people transitioned from agriculture to industry, the increase in inequality would decelerate, stop, and eventually reverse when the majority of the population worked in the industrial sector.

The new empirical studies of the early 1990s related to the Kuznets hypothesis but also to newer conjectures that predicted either positive or negative relationships between inequality and growth. Some theories, such as those of Alberto Alesina and Dani Rodrik, were based on political economy arguments, while others, such as the work of Abhijit Banerjee and Andrew Newman, were based on the effect of inequality in impeding access to credit.

This work generated a large demand for data on inequality that were internationally comparable and that spanned as long a time series as possible. While such data had long been available for income and growth, there was a paucity of global data on income distribution. Klaus Deininger and Lyn Squire, then at the World Bank, were pioneers in setting up and making available a compilation of inequality measures that were broadly comparable across countries and over time. Their dataset, based on household surveys, reported Gini coefficients—a summary measure of income inequality that ranges from 0, for perfect equality, to 100, when all income goes to a single individual, which is the most unequal of all possible distributions of income. Other similar, more comprehensive efforts followed, including that by the United Nations University’s World Institute for Development Economics Research (WIDER) center.

As Andrea Brandolini and Anthony Atkinson noted in the late 1990s, these comprehensive datasets had promise but also pitfalls. Some of the main shortcomings involved the lack of long and dense time series of inequality for many countries, especially developing countries. Cross-country comparability was also an issue. These factors made empirical work using these datasets difficult. Under the leadership of James K. Galbraith, the University of Texas Inequality Project (UTIP) was created initially as an effort to offer other sources of measures of inequality that addressed some of the shortcomings of these datasets.

UTIP’s initial proposal was to derive measures of within-country inequality using internationally comparable pay data, collected for industrial statistics released by the United Nations Industrial Development Organization (UNIDO). An issue with this dataset was that pay data were reported only at the industry level, and thus the within-industry distribution was unknown. Thus the use of the Theil index—the most widely used measure of a family of inequality measures that are perfectly decomposable into a within-group and between-group distribution—emerged as the most natural choice. For between-industry pay, the Theil index generated long and dense measures of inequality that were broadly comparable across countries.

In addition to releasing this global dataset, the work of UTIP involved exploring the methodological issues associated with the chosen measure of inequality. Using this dataset as well as data from national sources, Galbraith led innovative work on the interactions between inequality and several economic and political issues, ranging from conflict to financial crises. In fact, the use of the Theil index was expanded beyond global measures of interindustry inequality pay into other fields where issues of aggregation made the Theil index the natural measure to use. For example, when income or pay data are available at several levels of geographic aggregation (as in the United States, for example, at the national, state, and county levels), the Theil index enables the construction of decomposable aggregate measures into the contributions of the lower levels of aggregation. Insights into the dynamics of the contributions to aggregate inequality from lower levels of aggregation can then be established. Galbraith and colleagues at UTIP did pioneering work in using the Theil index to “aggregate upward.” For example, while inequality in the United States is often compared with that of other countries, it has rarely been compared with inequality in, say, Europe or European Union countries. By aggregating national measures of inequality upward, it is possible to construct a European-wide measure of inequality that may be more analytically appropriate to use in comparisons with the United States than that of individual countries.

More recently the UTIP-UNIDO measures of manufacturing-pay inequality were used, with other information, to estimate measures of household income inequality. This was accomplished by taking advantage of the systematic relationship between the UTIP-UNIDO estimates and those of Deininger and Squire. The residuals from this exercise provided a map to problematic estimates in the Deininger and Squire data, and the estimated coefficients enabled the construction of a new panel dataset of estimated household income inequality.

UNIVERSITY, THE

The modern social sciences, as well as all other forms of knowledge, are primarily studied and taught in universities. Not all the social sciences disciplines can trace their origins directly back to the twelfth century when universities first appeared. Many evolved indirectly from subjects taught at the original universities, such as law, logic, philosophy, and medicine. But the university’s main role in the development of the social sciences is primarily the result of manifold changes occurring in the second half of the nineteenth century. Demographic and urban growth, industrialization, democracy, and religious pluralism provided new arenas for academic inquiry and problem-solving and produced the array of disciplines commonly united under the heading of the social sciences. Economics, sociology, anthropology, demography, psychology, city planning, and scientific history came of age as autonomous university-based disciplines.

ORIGINS, CURRICULUM, AND SPREAD OF UNIVERSITIES

As a special type of educational institution, universities emerged almost unnoticed in three locations: Bologna, Paris, and Oxford. The circumstances were propitious. Trade had improved, cities were expanding, and municipal, imperial, and ecclesiastical authorities were in need of trained talent. Cities provided the necessary population, the facilities, the markets, and the career opportunities. Student fees, gifts, and ecclesiastical resources supported teaching, and universities were expected to help define and encourage religious belief. Until approximately the nineteenth century, most graduates of universities entered clerical careers, and most academics were ordained priests and ministers. Secularism and pluralism called into question many religious assumptions. At the same time universities embraced new forms of critical and scientific thinking, and as a consequence theology became just another subject rather than a primary focus, even within faith-based colleges.

In the beginning, the intellectual, philosophical, and scientific starting point of all teaching and learning was the corpus of encyclopedic writings mainly but not solely derived from Aristotle, preserved by Arabic scholars and transmitted to Italy in what historians have called the Renaissance of the Twelfth Century. This was the first of two revivals of ancient Greek and Latin learning in the Western world, the second commencing with the Italian Renaissance of the late fourteenth and fifteenth centuries. The medieval curriculum itself derived from the seven Roman liberal arts of logic, rhetoric, grammar, dialectic, astronomy, music, geometry, and arithmetic, but these were regarded as preparation for the professions of medicine, law (civil and canonical), and divinity rather than subjects in their own right. All were grouped into administrative structures called “faculties.” Although at first glance the seven liberal arts appear to be limited to mathematical and language studies, the process of teaching and expounding them furthered their development as multifaceted disciplines.

By the early modern period hundreds of universities had been founded in Europe by both secular and religious authorities, spreading from the Atlantic to Russia. During the ages of exploration Spain and Portugal established universities in their New World colonial territories, primarily to train imperial administrators and priests. Further north, the British settlements, beginning with Massachusetts, established university colleges to provide the colonies with an educated class. The first university in Japan came at the end of the nineteenth century, and in China in the twentieth. By the nineteenth century the utility of universities and college alternatives was so clearly accepted that governing elites associated their existence with the health of a modern bureaucratic state and economy.

NEW KNOWLEDGE AND STRUCTURES

There is a popular tendency to regard universities as conservative institutions and resistant to change. Academic costumes, rituals, and ceremonies provide an impression of unbroken tradition through the ages, as do the forms of teaching. But the conservatism of universities is merely
apparent. Sometimes deliberately, but often accidentally, the pursuit of learning by its very nature yields new conceptions, methods of inquiry, and startling intellectual movements. Two of the most closely studied are the scientific revolution of the sixteenth and seventeenth centuries and the transformation of the liberal arts during the Italian Renaissance.

In both cases examples can be found of innovations that grew out of the scholarly methods taught at universities. But there was also internal resistance. The heliocentric universe described by the Polish astronomer Copernicus (1473–1543) and publicized by the Italian physicist Galileo (1564–1642) undermined theological assumptions about the purpose, scale, and physical laws governing the cosmos. As a consequence, subsequent generations of scientists gravitated to newly establish royal societies where they could work unimpeded. In the same way, humanistic scholars using new critical methods of historical analysis founded academies where the liberal arts could be taught from a different perspective. Ruling elites were in favor. They desired education more closely focused on statecraft and better suited to the growing individualist cultures of the Renaissance. Yet intellectual cooperation between universities and the outside world never altogether ceased.

Disciplines alter over time, but so does the organization of teaching. Within a century or two of the founding of universities, colleges joined faculties as centers of instruction, improved discipline, and residence for students and instructors. Colleges were either freestanding or connected to existing universities, and among the most academically enterprising and successful were the Jesuit foundations of the Counter-Reformation. By the nineteenth century, however, colleges had largely disappeared from Europe, except for Oxford and Cambridge, where they remain, or in America with its distinct family of liberal arts colleges. Other examples of new administrative and teaching structures that arose, especially in the later centuries, are disciplinary departments, scientific laboratories, botanical gardens, observatories, art museums, marine biological stations, and ethnographical institutes. Libraries continued to buttress all pedagogical efforts.

Eventually the radical curricular changes associated with the early modern period were fully embraced by universities. As a consequence, the thrust of universities changed from places that mainly preserved and disseminated inherited learning, however modified in practice, to places devoted to discovering new knowledge. Research as the primary missions of universities is usually said to have started in Germany with the foundation of the University of Berlin in 1809; there were, however, earlier manifestations. Yet universal adoption of the research ethic was a phenomenon of the second half of the century, burgeoning in the century that followed.

**ACADEMIC FREEDOM**

The universities of the Middle Ages were genuinely international. The curriculum was similar, and the language of instruction was Latin. Students migrated to the leading centers from all corners of Europe. But the spread and popularity of vernacular languages, combined with political and religious divisions in the early modern period, altered the patterns of student mobility. Universities became more conspicuously national. Regarded as extensions of state power, the political loyalty of academics was under continual scrutiny.

Academic commitment to religious orthodoxy was also closely watched during the early modern period. The wars between Protestants and Roman Catholics created church and state alliances unknown in the centuries of a universal Christendom. But no matter how threatening the new conditions to academic freedom and institutional autonomy were, they did not compare to the calamities inflicted on universities, teaching, and freedom of inquiry by totalitarian regimes and nondemocratic governments of the twentieth century and afterward. The historical lessons clearly show that knowledge growth requires both external and internal freedom. Although universities originally developed as self-governing institutions with the right to own and dispose of property, they are only as free and independent as their societies and governments allow. And they are only as tolerant and open-minded in teaching and learning as are the devotion to those ideals of professors and students.

**BIBLIOGRAPHY**

UPWARD MOBILITY

Upward mobility is the experience of moving up into a more privileged economic position in society. Social scientists study the rates of upward mobility across different groups and societies because upward mobility is associated with notions of meritocracy and equality of opportunity. In a meritocratic or "open" society, all that is required for upward mobility is an education and hard work. Success in this type of society is determined by individual achievement rather than family background. In closed societies, on the other hand, there is little or no upward mobility. For example, children from working-class parents are likely to end up in working-class occupations themselves, and one's educational attainment is determined in large part by the educational achievements of one's parents.

There are two general types of upward mobility: intragenerational and intergenerational mobility. Upward mobility across generations, or intergenerational mobility, is commonly studied and often used as an indicator of a society's openness or fluidity. People also often experience upward mobility over the course of their own careers, which is known as intragenerational mobility. For example, someone may start out working in a low-paying job and then move up into a higher-paying job within the same company after a few years. In addition, a person may go back to school in midcareer to earn a college or graduate degree in order to move into a higher-status occupation, such as a professional or manager.

MEASURING UPWARD MOBILITY

Social scientists measure upward mobility in surveys in a variety of ways. In order to measure upward mobility, the researcher must decide on a measure of economic well-being or status. Several common measures of economic status include: individual earnings, family income, wealth, educational attainment, occupational status or prestige, and social class. Economists often measure the degree of mobility as the strength of the association between the income or earnings of fathers and their sons. A strong association between fathers’ and sons’ income indicates a low rate of upward mobility. On the other hand, a weak association indicates a high rate of upward mobility because children are not limited in their future economic success by the success of their parents. While these studies of intergenerational income mobility are informative, they are also limited in a few respects. First, focusing on income or earnings ignores other aspects of economic success, such as educational attainment and occupational prestige or status. Second, these studies also tend to ignore racial differences in upward mobility, which scholars such as Dalton Conley and Tom Hertz have pointed out.

Sociologists tend to measure upward mobility in terms of occupational or class “origins” and “destinations.” While the definition of class is contested in the literature, several definitions involve the nature of the employment relationship and the degree of skill, autonomy, and ownership someone has. This definition is similar to the one developed by Robert Erikson and John Goldthorpe in their book, *The Constant Flux* (1992). Sociologists within the status attainment tradition examine the importance of class origins in determining class destinations. Class origin, often measured by the father's occupation, is taken as an indicator of the degree of ascription or inherited success, whereas educational attainment is taken as an indicator of achievement or earned success. The relative importance of earned versus inherited economic status reveals the amount of potential there is for upward mobility. An increase in the importance of individual achievement regardless of class origin should translate into an increased rate of upward mobility. However, there is also the potential for downward mobility in an open society, which may be the result of economic downturns and organizational restructuring or individual decisions regarding education and different career paths.
UPWARD MOBILITY ACROSS COUNTRIES

Rates of upward mobility vary across countries. Under the rule of Mao Zedong (1893–1976) in China from 1949 to 1976, there was very little social mobility of any kind. As Yanjie Bian notes in his article in the Annual Review of Sociology, “it was rare to change an individual’s social position in Mao’s status hierarchy because of the rigid institutional walls” (2002, p. 104). In such a closed society, one is born into a particular economic status and destined to remain in that status group. However, with the economic reforms in China since 1978, social mobility is now possible and educational attainment is beginning to play an important role in determining occupational status.

The changing pattern of upward mobility in China highlights the importance of political and economic systems in explaining differences in mobility across countries. In general, advanced capitalist countries have greater potential for upward (and downward) mobility than socialist countries. Several formerly socialist countries in central and eastern Europe have begun to experience increasing mobility and inequality since the revolutions between 1989 and 1991. However, the transition from socialism to capitalism does not necessarily mean that the potential for upward mobility will increase. As Theodore Gerber and Michael Hout discuss in their 2004 article in the American Sociological Review, there is evidence that social mobility actually declined during Russia’s market transition in the 1990s. Gerber and Hout found that the association between class origins and destinations strengthened during the transition to a capitalist economy in part because the deregulation of the state labor market allowed elites to pass on benefits to their children with greater ease (2004, p. 696).

There are other scholars, such as Erikson and Goldthorpe, who contend that advanced industrial countries with similar occupational structures will have similar rates of social mobility. According to this view, all modern societies will display some association between class origin and class destination. This does not suggest that upward mobility does not exist. However, it is limited by certain laws, customs, and norms that serve to reproduce systems of stratification across generations. Despite these similarities across countries, many scholars agree that countries such as Sweden exhibit a higher degree of social mobility than the average country, and others, such as the United States, exhibit lower degrees of mobility (Solon 2002). However, the reasons behind these differences are still not clear, and the issue is complicated even further by measurement differences across countries. A substantial amount of research remains to be done on the topic of country differences in upward mobility.

RACE AND UPWARD MOBILITY

Rates of upward mobility also vary substantially across different social groups within countries. Different racial and ethnic groups in the United States have dramatically different experiences with upward mobility. In his study of race and economic mobility, Tom Hertz finds that the association between parents’ and children’s income “is driven to a large extent by black families’ especially low rate of upward mobility from the bottom of the income distribution” (2005, p. 165). The “rags to riches” transition popularized by the Horatio Alger novels is twice as likely for whites as it is for African Americans in the United States. Being born into a family in the bottom income bracket has very different implications for whites and African Americans. For African Americans, it means that one is likely to end up living in a low-income household as an adult as well. However, whites have a fair chance of moving up into at least the middle of the income distribution later in life. Therefore, the United States is a fluid and open society for whites with a lot of potential for upward mobility. However, for African Americans, it is often a rigid and closed society with little potential for mobility.

Explanations for racial differences in social mobility in the United States range from racial discrimination in the educational system and the labor market to differences in individual aspirations and abilities. In his book, Being Black, Living in the Red (1999), Dalton Conley examines racial differences in several indicators, such as income, education, and family structure. Conley’s major conclusion is that racial differences in income and wealth are primarily due to the dramatically different class backgrounds of whites and African Americans. In particular, differences in wealth between white and African American families are responsible for subsequent racial differences in the labor market. As Conley notes, it is easier to pass on wealth across generations than income or education (1999, p. 14). Solutions to the problem do not center on increasing access to educational institutions. According to Conley, what is needed is a race-based asset policy that promotes property ownership for African Americans (p. 138).

Research on upward mobility has benefited from recent studies that incorporate racial differences. However, there are several limitations to these studies. The most important limitation is the absence of any discussion of the mobility patterns of Asians, Latinos, and other racial and ethnic groups. Latinos are now the largest racial or ethnic minority group in the United States, and an investigation of the potential barriers they face to upward mobility is needed.
UPWARD MOBILITY OVER TIME

Upward mobility also changes over time. However, there is a debate in the literature about how much change has occurred and why. According to the liberal theory of industrialism, rates of social mobility should converge over time across countries as they reach similar levels of industrialization. Richard Breen and Jan Jonsson observe in their 2005 article in the *Annual Review of Sociology* that there is evidence of at least modest increases in mobility in several different countries since the 1970s. Additionally, the relationship between class origins and destinations may be weakening over time in several countries, which suggests greater potential for upward mobility in the future based solely on individual achievements. However, other scholars, such as Erikson and Goldthorpe, see temporal changes in social mobility as short-term fluctuations rather than long-term trends (1992, p. 36).

The trajectory for upward mobility in the future is complicated by several different factors. First, the strength of the association between class origins and destinations will play an important role. Despite the popularity of the “rags to riches” stories from Horatio Alger novels in the late 1800s and the image of most modern societies as meritocracies, family background continues to have a strong influence on one’s economic success today. Growing up in a wealthy family with educated parents puts children in an advantaged position because of the resources and values that are passed down, which children from economically disadvantaged backgrounds often do not receive. Therefore, as long as class inequality persists, so too will the limits on upward mobility.

However, there is also reason to believe that rates of upward mobility may increase in the future in several countries. Education is increasingly important in the postindustrial world, and the worldwide expansion of educational opportunity may help to provide opportunities for people to move up into higher-status occupations regardless of their social origins. Even in Communist countries such as China, educational attainment is increasingly responsible for what type of job someone works in and the income they receive. Although equalizing access to education would increase the potential for upward mobility, it would not lead to completely open or fluid societies. Equality of opportunity does not guarantee an equal or “just” society. It merely guarantees “an equal chance to leave the less fortunate behind in the personal quest for influence and social position” (Rawls 1999, p. 91). Inequalities of condition, such as wealth inequality, are likely to persist and limit the potential for upward mobility. Only policies aimed explicitly at limiting the degree of inequality in property and assets, such as redistributive taxes on wealth, are likely to make a significant difference.

URBAN RENEWAL
Urban renewal is a cooperative effort by public officials and private interests to improve a city's structural, economic, and social quality. Major American cities were economically and socially devastated by the stock market crash of 1929 and the ensuing Great Depression of the 1930s. Most cities had narrow tax bases that relied excessively on property tax revenues, which sharply declined because of widespread business failures and mortgage foreclosures. High rates of unemployment, poverty, and homelessness overwhelmed scarce local resources and contributed to a decline in essential local services, such as public schools and police protection.

The urban-centered New Deal programs of President Franklin D. Roosevelt (served 1933–1945) addressed the immediate economic crisis of American cities instead of their long-term improvement. In particular, New Deal programs such as the Works Progress Administration (WPA) and Public Works Administration (PWA) used public-works jobs to reduce unemployment, stimulate local economies, and subsidize state and local relief for the unemployable poor. The Social Security Act of 1935 included unemployment insurance and Aid to Dependent Children (ADC). Nonetheless, these New Deal programs did cause some major long-term changes in the structure and design of major cities, such as the construction of the Triborough Bridge in New York City and a new city hall for Houston, Texas.

The Housing Act of 1934 created the Federal Housing Authority (FHA), and the U.S. Housing Authority was established in 1937. These federal agencies eventually became the major bureaucratic components of the U.S. Department of Housing and Urban Development (HUD), created in 1965. Influenced by the perspectives of local banking, real estate, and construction interests, the FHA encouraged and solidified the practice of redlining, in which poor African Americans and Latinos were segregated in federally subsidized public housing projects and experienced discrimination in the sale and rental of private housing in white neighborhoods.

During World War II (1938–1945), major cities experienced severe housing shortages and strains on local public services and infrastructure. There was a sharp increase in the number of poor and working-class residents, especially African Americans from the South and whites from rural areas, who moved there to work in defense industries. There also existed a scarcity of materials and labor for civilian construction needs.

The Housing Act of 1949 was the first act of Congress that included federal funds and guidance for urban renewal in addition to providing federal funds and regulations for building more affordable private and public housing and clearing slums. This law also had the effect of continuing and expanding the practice of redlining as more whites, assisted by federally subsidized home mortgages for veterans, moved from cities to suburbs and a larger percentage of urban populations consisted of low-income African Americans and Latinos.

During the 1950s, other federal policies, especially the interstate highway program, accelerated the economic and social decline of major cities, especially in the Northeast and Midwest, as more middle-class homeowners lived in suburbs and commuted to cities for work or moved to growing metropolitan areas of the South and West. Under President Dwight D. Eisenhower (served 1953–1961), the federal government financed a limited number of competitive block grants to help cities revitalize their downtown business districts and clear slums. Led by Mayor Richard Lee, the ambitious urban renewal project of New Haven, Connecticut, was a prominent beneficiary of this federal aid. Toward the end of his presidency, however, Eisenhower vetoed Democratic legislation intended to economically revitalize chronically depressed cities and rural areas on a more expensive, comprehensive basis.

By the 1960s, major urban renewal projects had been completed in Pittsburgh, Boston, and New Haven. Under the leadership of parks commissioner Robert Moses, New York City continued to construct new highways, expressways, bridges, tunnels, office buildings, and public housing and to force the migration and dispersal of residents and small businesses from working-class and poor neighborhoods. Jane Jacobs's 1961 book, The Death and Life of Great American Cities, galvanized greater public opposition to urban renewal policies, especially in New York City. Jacobs argued that comprehensive, aggressive urban renewal policies, like those of Moses, often destroyed the social cohesion and quality of life of urban neighborhoods. Critics of urban renewal referred to it as "Negro removal" for adversely affecting urban black neighborhoods in particular. Poor and elderly blacks were forced to move to public housing projects while middle-class black professionals and business owners often moved to suburbs.

Partially influenced by Jacobs, some of the Great Society programs of President Lyndon B. Johnson (served 1963–1969) tried to ameliorate the social problems
caused or worsened by urban renewal. Programs such as Model Cities, Head Start, Community Action, Legal Services, and Job Corps were intended to help urban residents, especially low-income African Americans and Latinos, to improve their social, economic, and educational conditions and redress their grievances against local officials and businesses. The Fair Housing Act of 1968 addressed the increasing residential segregation of poor African Americans and Latinos in major cities by prohibiting racial discrimination in the sale and rental of both public and private housing. Nonetheless, major race-related urban riots occurred during the 1960s.

The Republican administrations of presidents Richard M. Nixon (served 1969–1974) and Gerald R. Ford (served 1974–1977) eliminated or reduced funding for the most urban-oriented Great Society programs. However, they increased total federal aid to cities by introducing General Revenue Sharing (GRS) and Community Development Block Grants (CDBG). GRS and CDBG increased federal aid to cities while reducing federal control, and CDBG gave local business interests greater discretion in using CDBG funds for urban renewal. By the 1980s, the percentage of local government budgets consisting of federal aid peaked at 30 percent.

Determined to reduce federal spending and intervention in urban affairs, President Ronald W. Reagan (served 1981–1989) eliminated GRS by 1987 and reduced the number of block grants. Instead, the Republican administrations of Reagan and President George H. W. Bush (served 1989–1993) emphasized the use of tax credits and other market-based incentives to encourage the ownership of public housing units by their residents and to subsidize the construction of affordable private housing through HUD grants. By 1990 the percentage of local government budgets derived from federal aid declined to 17 percent.

With a Republican-controlled Congress during most of his administration, Democratic president William J. Clinton (served 1993–2001) did not introduce a major new role for the federal government in urban renewal. Instead, Clinton's policies sought to improve the quality of life for the urban working poor, especially racial and ethnic minorities, through earned income tax credits, the Welfare Reform Act of 1996, greater access to Head Start and public health services for poor, urban children, and more federal aid for law enforcement and public safety. By 2000 federal aid as a percentage of local government budgets had modestly increased to 20 percent. With steady economic growth during most of the 1990s and early twenty-first century, “gentrification” became the primary objective of urban renewal as local officials and business interests sought to attract young, affluent professionals as new residents and more tourists, conventions, and cultural activities to downtown areas.

URBAN RIOTS

A riot happens whenever a crowd engages in collective violence such as beatings, murder, looting, or arson. Riots are far more likely to occur in urban than in rural areas because the density of population increases the supply of potential participants, as well as targets of attack. The state’s role in a riot ordinarily is to squash it using police or military force, but in some instances the police or government officials may provoke a riot for political ends. Generally, countries have laws against rioting, as well as rules of engagement that govern the use of deadly force to quell a disturbance. A riot may spread through media reports or if rioters contact their compatriots in other cities, urging them to start a disturbance. The odds of rioting may be increased or decreased by nature: A hot summer night may cause tempers to flare, whereas a thunderstorm may disperse a crowd otherwise bent on mayhem.

Riots have underlying and proximate causes. The underlying causes are grievances, real or perceived, that rioters hold against social or political institutions, usually (but not always) where the riot occurs; or against other groups of people on racial, ethnic, or religious grounds. The proximate cause can almost always be identified after the fact—an incident of police brutality or a racial, ethnic, or religious slur. Riots may have economic, social, or political consequences. A riot of a majority against a minority may cause the latter to move away from particular neighborhoods in a city or to different cities. A riot
may change expectations of future economic growth in a city, causing capital to be allocated elsewhere.

Urban riots have been widespread throughout modern history and across countries. Riots over food shortages were common in seventeenth- and eighteenth-century Europe. Riots fueled by religious conflicts have occurred quite regularly in the Middle East, India, and the Far East. As discussed below, racial rioting erupted at unprecedented levels in the United States in the 1960s. In the 1980s urban riots broke out in England. In the early twenty-first century, rioting by disaffected minority youth was particularly violent in suburban areas of French cities.

Governments react to the aftermath of riots in diverse ways. A dictator may react by repressing the dissenting minority harshly, although this may entail a subsequent risk of revolution. In democracies rioting may also influence the course of national politics by enhancing the political clout of politicians on the left or right. In the United States, for example, Spiro Agnew, a conservative Republican from the state of Maryland, came to prominence on a “law and order” platform in the aftermath of riots in Baltimore in the 1960s. Democratic governments may also react by creating special commissions to study the causes of the rioting such as the famous Kerner Commission Report (Kerner et. al. 1968), which studied the causes of the 1960s riots in the United States. Ameliorative policies may be adopted in the hope of stemming future violence. Richard Nixon’s so-called “Black Capitalism” agenda (Weems and Randolph 2001) and expansion of affirmative action in the early 1970s can be seen in this light.

1960s RIOTS: THE UNITED STATES

The United States possesses a long, terrible history of racial rioting. Until World War II, the vast majority of urban riots involved white-on-black violence. Perhaps the most infamous example during the nineteenth century was the 1863 riot in New York City, during which immigrants angry over the Civil War draft in the North attacked and killed scores of African Americans. As African Americans left the rural South and moved to Northern cities they increasingly competed with whites for housing and jobs. Racial tension sometimes escalated into white-on-black riots such as those in St. Louis and Chicago in 1919. In 1943 riots broke out in Newark and Detroit that in character bear a resemblance to those that occurred in the 1960s, including clashes between African Americans and police, as well as looting and arson of businesses in African American neighborhoods. Even when viewed against the backdrop of the 1940s riots, those occurring in the 1960s were without historical precedent. From the early 1960s through the early 1970s, hundreds of riots originating in African American neighborhoods broke out in American cities. Since the 1960s the United States has not been completely immune to racial riots, as examples in Miami (1980), Los Angeles (1992), Cincinnati (2001), and Benton Harbor, Michigan (2003), attest.

The standard academic definition of a 1960s race-related riot, as originally put forth by Spilerman (1970, 1971), was a “spontaneous” occurrence with a minimum of thirty participants, some black, that resulted in violent outcomes, such as arson, looting, or death. With this definition in mind, social scientists have collected information on the location, timing, and severity of the 1960s riots. Currently, the most comprehensive data set is that collected by Carter (1986), which covers the period 1964 to 1971 and includes the dates and locations of more than 700 civil disturbances, as well as numbers of deaths, injuries, arrests, and occurrences of arson. The peak years of riot activity were 1967 to 1969, especially 1968 in the aftermath of the assassination of Martin Luther King Jr. Most riots were not severe, in the sense of widespread loss of life or property destruction, but a small number were extraordinarily violent. By far the deadliest riots were those in Detroit in July 1967 (43 deaths), Los Angeles in August 1965 (34 deaths), and Newark in July 1967 (24 deaths).

Social scientists have long tried to identify city-level factors associated with the incidence and severity of the 1960s riots. In general, after accounting for each city’s black population size in 1960 and for region, little or no variation in incidence and severity can be accounted for by pre-riot city-level measures of African Americans’ absolute or relative (black-to-white) economic status. The point is not that the 1960s riots had no underlying causes but rather, if the black population in a given city was of a sufficient size, a riot could happen at almost any time in the mid-to-late 1960s if there was an appropriate spark. Most sparks were local—for example, in the Watts, Los Angeles, riot in 1965, the arrest of an intoxicated black motorist led to a wider altercation with neighborhood residents and eventually a huge riot. By contrast, the King assassination was a national spark that had the potential to incite rioting across the country.

The King riots figure importantly in two recent studies of the economic impact of the 1960s riots in urban areas (Collins and Margo 2004a, 2004b; King 2003). In the several weeks following that assassination, more than 100 riots erupted. However, riots did not occur everywhere, and a key factor in determining the likelihood and severity of a post-King riot was the level of rainfall. A high level of rainfall in April 1968 significantly reduced rioting and is a source of exogenous variation across cities. Using predicted severity based on rainfall, Collins and Margo show that the various economic outcomes for African Americans and police, as well as looting and arson of businesses in African American neighborhoods.
Americans—for example, median household income, employment rates, and the value of owner-occupied housing—declined sharply between 1960 and 1970 in cities that experienced severe riots. Moreover, these declines persisted and in some cases worsened in the 1970s. Collins and Smith (2007) extend the cross-city analysis to a case study of Cleveland, showing that black neighborhoods that bore the brunt of the rioting experienced economically significant and persistent declines in property values and population that were not continuations of trends in place prior to the violence.

THE FRENCH RIOTS OF 2005
In the United States the poor tend to live in the central cities of metropolitan areas, but in France (as in other western European countries) the poor are concentrated in suburban rings around a wealthy core. Since the 1970s French suburbs have been increasingly populated by immigrants from North Africa (the Maghreb), sub-Saharan West Africa, and the French West Indies. Most immigrants live in public housing built in the 1950s and 1960s. Their list of grievances is long—high unemployment, racism, police brutality, and inadequate educational opportunities.

In the fall of 2005, serious rioting broke out in the town of Clichy-sous-Bois in suburban Paris. The spark that caused the riot was the accidental electrocution of two minority youths who were fleeing the police. News of the electrocution spread quickly, and rioting commenced. The principal form of violence was arson, primarily directed against automobiles, but also some schools, day care centers, and businesses. As news of the violence was broadcast on French television (indeed, throughout the world) and by the Parisian rioters using the Internet and other electronic media, rioting spread to the suburban peripheries of other French cities. Nationwide, the rioting lasted for two weeks before finally petering out. On the first anniversary of the riots there were sporadic outbreaks of violence, but no full-scale reoccurrence of rioting.

URBAN SPRAWL
Urban sprawl may be defined as the low-density, haphazard housing development that spreads out around modern towns and cities. The terms sprawl and suburbia are often used interchangeably and pejoratively to describe inferior forms of development, compared, presumably, with the ideal model of the compact urban form of the historical European city. Urban sprawl is typified as “bad,” physically because it is so spread out with a lack of local facilities; socially because of boredom among residents and a lack of community identity; economically because of residents’ dependency on the motorcar and thus upon politically sensitive international oil supplies; and environmentally because of the impact on agriculture and native habitats and the increased generation of pollution and urban waste.

Until the nineteenth century, towns and cities were generally limited in extent because local facilities and employment had to be within walking distance of home, while longer journeys utilizing horse transport were time-consuming and often dangerous. The coming of the railways enabled people to “escape” the city and live further from their workplace. But residential density and expansion were still constrained by accessibility to the nearest train station. The development of the motorcar, and the growth of public transport omnibus routes, meant that transport was no longer limited to fixed-track systems. Potentially, people could live anywhere. Factors that hastened suburban sprawl included cheap vehicle fuel and mass production of motorcars, mass commercial house-building, cheap mortgages, weak urban-planning control, a cultural desire to have “a home of one’s own,” and the
trend for aspiring households to abandon the inner city and move “up and out.”

While suburban development was rapid, extensive, and encouraged in North America, Western European governments were anxious to control expansion because their countries are so much smaller and there is simply not the space to expand or to give the motorcar and road-building projects unfettered freedom. For example, the land area of the British Isles fits into Texas alone six times, and France fits four times. By the 1930s, regulations were being introduced to control urban sprawl, to protect farmland, and to prevent the tentacles of “ribbon development” house-building alongside intercity highways, invading the countryside. Retaining enough agricultural land to be self-sufficient in food was recognized as vital following World War II (1939–1945) shipping blockades of the British Isles. In the postwar period, strict spatial-planning legislation was introduced to prevent the town from engulfing the countryside. For example, “green belts” were designated around major cities to act as cordon to prevent further outward development.

Recognition of “urban sprawl” as a problem is relative, depending on the size of a country’s population and its land area. Some countries have maintained a laissez-faire approach toward urban sprawl. In New Zealand, a country of comparable size to Britain but with only four million inhabitants (in contrast to Britain’s fifty-nine million), large tracts of low-density, single-story “bungalow” development surround the major cities, and new “subdivided” residential developments have mushroomed with little apparent planning control within scenic rural areas. Although there may be lots of space to expand, environmental considerations now have to be taken into account under resource-management planning legislation. Likewise, in Australia there are increasing demands to protect koala bear habitats from encroachment by house builders. Houses built on the edges of cities alongside wilderness areas are in danger of being destroyed by forest fires, which can take hold rapidly during the dry season, as has been witnessed in recent years on the outskirts of Sydney, Australia; San Diego, California; and also in southern France and Portugal.

The low-density, spread-out nature of suburban sprawl, creates many practical problems too. Residents are completely dependent upon the motorcar to get from one land-use and amenity to another. Distances are often too great to contemplate walking to school or work. Retail provision is likely to be in an out-of-town shopping mall (Kunstler 1994), rather than along a “Main Street” (as fondly re-created by the Disney Company in the town of Celebration, Florida). Some North American housing developments are designed with no footpaths or sidewalks alongside the roads, making it impossible for residents to walk around their area. Land-use zoning regulations, introduced to protect the quality of an area, often result in miles and miles of nothing but housing with no other uses allowed. Socially, such areas are just “dormitory suburbs,” which people leave each day to commute downtown to work. Many sociological studies, including feminist research (Hayden 2002), have shown that housewives, mothers, children, young teenagers, and the elderly may feel trapped in the suburbs, with little chance of accessing the outside world. There is little room for social diversity and minority considerations (Reeves 2005).

Environmentally, urban sprawl is not sustainable either. Major infrastructural investment is required to provide roads, water, sewerage, drainage, garbage disposal, power, and other utilities and services to dispersed housing developments. Water shortages and power outages, exacerbated by climate change as a result of global warming, have become a common feature of some such residential areas (Lees 2004).

Urbanization and suburbanization are major global trends (Greed 2002). The rate of growth is far greater in the developing world, where a less affluent but pervasive form of urban sprawl is taking place: namely, the shanty town, as found, for example, in Latin America, where both Mexico City and São Paulo, Brazil, have populations of over twenty million. Unregulated development may cover a larger land area than the existing city, as people move in from the countryside to seek jobs in the town. Unlike affluent Western urbanization, third-world sprawl is generally high-density, socially deprived, lacking infrastructure, and relatively carless. But, unlike Western suburbanites, barrio dwellers may have a strong sense of community and local neighborhood identity, albeit brought about by shared adversity.

What are the alternatives to urban sprawl? There is a need to create cities that are more environmentally, economically, and socially sustainable. European planners have suggested the ideal of “the city of everyday life,” which would be based on higher densities, multiple functional local centers, walking distances, and public transport (Greed 2002). Likewise, the postmodern “new urbanism” in North America promotes a greater sense of community and a more human scale of design (Ellin 1999). Meanwhile planners stress the importance of urban renewal, infill, and higher densities. But the Anglo-American urban cultural tradition still favors low-rise, low-density housing solutions, in contrast to the European tradition of high-density apartment living and Asian high-rise solutions. The majority of the populations of the United States, the United Kingdom, Canada, Australia, and New Zealand live in the suburbs. The reality is that ordinary people with families want to live in the suburbs, and are willing to put up with long congested commutes to work to do so. But suburban sprawl is not a
sustainable option. The challenge for the future is to create more compact cities, which are nevertheless pleasant and acceptable places to live, work, and relax.

URBAN STUDIES

Urban studies is the umbrella for several disciplines engaged in studies of the city, including sociology, geography, economics, political science, anthropology, urban planning, architecture, and urban design. Practitioners of these linked disciplines study urbanization and issues surrounding metropolitan dynamics, the process that links cities with the wider economy, their governance, and their spatial structure and change expressed in physical, economic, social, and cultural dimensions. These disciplines use distinctive epistemologies in understanding the city, but the issues they address typically cut across disciplines.

APPROACHES, CONCERNS, AND DISCIPLINES

The major traditions or approaches in urban studies are locational analysis, spatial network analysis in the management of cities, and sociocultural, institutional, political economy, and postmodern methods (Paddison 2001). Locational analysis, identified primarily with the work of urban economists and urban geographers, is concerned with intramural spatial patterns of urban land use and the accessibility of central business districts. William Alonso (1964) developed the seminal bid-rent theory for urban land markets. Network studies examine the spatial distribution of systems of cities and their specialization and development. Walter Christaller’s (1933] 1966) central place theory and subsequent works by August Lösch ([1944] 1954) and Walter Isard (1956) are the key early works in this urban studies thread. More recent studies of spatial networks focus on the formulation of linkages in the world economy, urban economic restructuring, and globalization (Friedmann and Wolff 1982; Sassen 1991).

Sociocultural and institutional approaches have been developed by urban sociologists, urban anthropologists, and political scientists. Key elements of these approaches are understanding the meaning of urban social life, grasping human ecology, analyzing social areas, using techniques of factorial ecology, and conducting empirical studies on “ways of life.” Early social scientists contributing to these trends included Ferdinand Tönnies ([1883] 1995), who defined community and society ideal-types; Max Weber (1905), who identified ideal city-types as loci of civilization and historical change; and Lewis Mumford (1938), who pioneered the study of urban culture.

The Chicago School, the first school of urban analysis, was established in the 1920s in the Sociology Department of the University of Chicago. It was uniquely concerned with urban life and developed the human ecology approach to describe the structure and processes of urban ethnic neighborhood change. Robert Park (1916, 1952) derived principles of competition, succession, and invasion by which groups use or dominate city spaces. Members of the Chicago School studied Chicago as an urban laboratory. Along with Ernest W. Burgess and Roderick D. McKenzie, Park (1925) explored social patterning and the concentric patterning of urban growth. Louis Wirth (1938) formulated principles of size, density, and heterogeneity and defined urbanism as a way of life. Eshref Shevky and Wendell Bell (1955) contributed to the development of social analysis by linking urban industrialism to sociospatial differentiation. Duncan Timms (1971) applied factorial ecology techniques to identify sociospatial patterning.

Ethnographic studies include research on the distinctive “ways of life” of different urban marginal groups (including hobos, gangs, and immigrants), the techniques of self-reporting life histories (Thomas and Znaniecki 1918–1920), and the utilization of official data, including census reports and housing/welfare records, to create maps of the location and range of such urban problems as crime, poverty, and juvenile delinquency. W. E. B. Du Bois (1899) pioneered the use of direct surveys, while E. Franklin Frazier (1932) charted new ground in understanding the dynamics of urban social classes. Later ethnographic studies on gangs and immigrant groups in Boston and Chicago are well-known examples of the application of the participant-observer methodology developed by the Chicago School (Anderson 1978, 1990; Whyte 1943). These techniques have now become standard in various urban studies fields, the former in economics and geogra-
phy and the latter in sociology and anthropology. Jane Addams's (1910) fieldwork on immigrants and on the living conditions of African Americans in segregated cities added considerable voice to the movement for direct policies for urban reform.

The institutional approach explores community life, community power, and urban power. Research on the development of communities includes the detailed empirical studies of community life and community power by Robert Lynd and Helen Lynd (1929, 1937). Focused community studies by Michael Young and Peter Willmott (1957) and the early community/urban power studies of the 1960s, Floyd Hunter's (1952) study of local elites, and Robert Dahl's (1961) formulation of dispersed/pluralist sources of power established the core of metropolitan governance studies. John Rex and Robert Moore (1967) researched the role of institutions and agency in influencing social outcomes. R. E. Pahl (1970) formulated urban managerialism/gatekeeping as control mechanisms for access to key resources. Clarence Stone's (1989) regime analysis argued that the operation of metropolitan politics in the Atlanta area was based on political networks among the fragmented metropolitan governments and that managing these networks had become the essence of governance. Addressing class stratification in urban areas with this approach is indirect; if cities succeed in the global marketplace through well-developed urban management, the theory argues, prosperity will trickle down to the urban poor.

The political economy tradition links urban challenges to underlying inequalities in power and property in the process of urban development. Marxist analysis of urban issues and development (Engels [1844] 1973; Harvey 1973; Gordon 1978), the analysis of urban government as a local state (Cockburn 1977), evaluations of urban ideology and collective consumption conflicts (Castells 1977), and applications of dependency theory to urban problems are examples of this vital trend in urban studies. This approach generally argues that the rigid stratification in cities is a reflection of the broader class structures in society and that revolutionizing national and international class relations is a requirement for significant urban transformation.

Researchers from urban planning, urban design, and architecture focus their concerns on the management and structure of cities. Modernist visions of the city were applied in the New York Regional Plan (1922) and Greater London Plan (1944). William Whyte (1955) studied public use of urban parks and plazas to identify the types of architecture and spatial design that promote a certain pattern of behavior. "New Urbanism" considered American small towns as imagined urban models, where busy and lively sidewalks help cities thrive as safe and healthy places. According to Jane Jacobs's (1961) "vibrant city" concept, lively street life supports a creative and diverse economic base, but rigid planning smothers urban social life and entrepreneurialism. Where planners have called for detailed planning processes, usually engaging the affected communities, economists have argued for a greater role for market forces in determining the location and density of activities. Both generally accept existing patterns of class stratification.

Postmodern approaches confront the assumptions of positivism and the theory of modernist planning and study different aspects of city life. Postmodernists have analyzed cities as centers of consumption (Mort 1996), centers of recreation (Hannigan 1998), and centers of image (Gottdiener 1995). Jane M. Jacobs (1996) developed the concept of "representational cities," where messages encoded in the environment can be read as texts. Postmodernists, however, offer few concrete suggestions on ameliorating the conditions of the poor; increasing diversity and participation in social life, they believe, would be an important component of enhancing the quality of life for all city dwellers.

**DIFFERENTIATION, DISPLACEMENT, EXCLUSION, AND GLOBALIZATION**

Urban scholars today are tackling the issue of globalization's impact on urban spaces and populations from many perspectives, building on the field's past insights into such urban processes as the differentiation of urban populations due to social and economic inequalities, the displacement of the less affluent, and the exclusion of the poor from public amenities. Many urban scholars now feel that the ever-growing world-wide mobility of capital and labor—globalization—is causing populations to sort themselves into rigidly segregated global class hierarchies.

Cities have been in the process of constant economic restructuring since the beginning of industrialization. John Kain's (1968) "mismatch hypothesis" and William J. Wilson's works (1987, 1996) on the "underclass" provided frameworks within which to understand suburbanization (in both economic and sociologic dimensions) as a process that increases differentiation and exclusion. The emergence of employment centers or "edge cities" (Garreau 1991) in the suburbs showed that the loss of low-skill jobs in the central cities is not easily reversible. Globalization, driven by international flows of capital and information, has created a new system of city networks (Castells 1989; Sassen 1991).

Thomas Sugrue (1996) documented how economic restructuring in Detroit has been extremely painful and dislocating for African Americans who lost their middle-class jobs in the automotive industry. Lack of economic
opportunities increased the size of the underclass in Detroit. Saskia Sassen (1991), H. V. Savitch and Ronald Vogel (1996), and John Mollenkopf and Manuel Castells (1991) showed that New York City has become a “dual city,” where skilled workers work in the specialized industries and immigrant workers take lower-paying service jobs and live in distinctly separate urban environments. Globalization coupled with urban renewal programs resulted in gentrification or displacement of some poor inner-city urban residents by higher income groups. Mike Davis (1990) argued that globalization has also opened urban land markets to global capital. Los Angeles, for example, restructured its industrial base and maintained its prosperity through participation in the Pacific Rim postindustrial order (Scott and Soja 1996), but the associated flood of capital from Asian countries increased land prices and made housing unaffordable for virtually all middle-class residents in Los Angeles. Globalization and privatization of public space in Los Angeles have excluded the lower and middle classes from most of the urban space.

Urban studies today continues to grapple with such challenges. Economists urge a reliance on market forces for improvements, while planners call for detailed “smart growth” plans. Political scientists focus on enhancing and democratizing governance as the pathway to progress, while institutionalists urge the federal government, not just the locality, to address the underlying social ills confronting the poor in cities. Similarly and more radically, political economists argue that urban challenges cannot be successfully addressed as long as the national class structure maintains an unequal, exploitative regime. Taken as a whole, then, urban studies is a terrain of contention among schools of thought, with many alternative policy recommendations to address the challenges of the city.

Urbanity

---

**URBANITY**

Over the course of the nineteenth century in Europe and North America, urbanity came to be conceived as a personality trait. According to Richard Sennett (1974), public experience outside the private sphere of the home became an obligation for the self-development of men. Conversing in cafés or walking the busy streets, just like traveling, was a means to acquire sophistication and to become comfortable with diversity. Urbanity, cosmopolitanism, and sophistication were almost synonymous. For women, on the other hand, exploring the public sphere was considered immoral. Moving about the city alone and freely was associated with loose sexual behavior. It was in the sphere of the bourgeois home in the city that women acquired the manners and accent of urbanity. Present-day standards of politeness, such as the notion that each person has the right to be left alone when in public or norms on proper English and proper dress, were derived from the social control of the urban bourgeois home.

Indeed, urbanity is often conceived as the cultural capital of higher social classes. As a personality trait, it is used for exclusion in jobs and for residential segregation. For instance, the speaking accent of youth living in the French banlieue (suburbs) acts as a serious barrier to employment in a discriminatory environment. In addition to their relegation in housing projects outside cities, these youths are not seen as endowed with enough urbanity and sophistication to work and they are often tagged with a lack of civility.

For Pierre Bourdieu (1979), cultural capital provides people with a structure of predispositions transmitted by their family; urban, white, middle-class youth would thus be better equipped to succeed than their poor, suburban counterparts. There are three forms of cultural capital, each of them closely associated with the notion of urbanity. Firstly, embodied capital refers to investments in self-improvement; it is thus focused on urbanity as a personality trait that can be developed. Secondly, objectified cultural capital is represented by material objects such as a nice car or a house in a trendy neighborhood; it is thus closely related to the politics of space (who has the right to be in the city?). Thirdly, institutionalized cultural capital provides certain people with access to decision-making powers affecting everyday life in the city.
White, middle-class, urban dwellers endowed with these three forms of cultural capital have a discriminatory and exclusionary impact on other city dwellers. They can shape the city to their own image. Derelict landscapes in central cities are regenerated, pushing away poorer residents for processes of gentrification. The revamping of Times Square in New York City, for instance, is an example of what Neil Smith (1996) calls revanchist urbanity, whereby the white middle-class appropriates spaces in the city for their own pleasure and the fulfillment of their own urbanity. In the name of economic growth and safety, former New York mayor Rudy Giuliani went on with this model of what Sharon Zukin has called “pacification by cappuccino” (1995, p. 28), eliminating greasy mom-and-pop joints and other venues that were not attractive to the white middle class.

As a personality trait enhanced by spatial practices and institutional power, urbanity is used as a means of exclusion. However, more and more voices are rising to claim other forms of urbanity that would not be linked to class and ethnicized cultural capital. This became particularly visible in the wake of the worldwide urban revolts of the late 1960s. Henri Lefebvre (1968) wrote then about the rights to the city—that is, the right to be in the city and to have decent living conditions, but also the right to define the codes and norms of social life in a manner closer to everyday practices than to technocratic power.

In fact, according to Lefebvre (1970), after the agricultural, mercantilist, and industrial ages, we are now going through an urban revolution. This does not only mean that more than half of the world population lives in cities that cover more and more land, but also and mostly that the way we conceive of the world has become urban. For Lefebvre, personalities, economic behavior, spiritual beliefs, modes of social interaction, all aspects of human life have become urban. Urbanity, in this second definition, is not confined to a personality trait of the white middle class but is a general characteristic of the world since the 1970s. Even for peasants in a country of the “global south,” Lefebvre would argue, urbanity is part of their life, their values, and their mental schemes.

In this sense, urbanity can be defined by a set of distinctive social characteristics, regardless of geographical location. Diversity of people, beliefs, and histories is the most important of these characteristics. Whether it is celebrated, commercialized, tolerated, or oppressed, diversity is a trait of urbanity that is very different from rurality (which is often associated with homogeneity). Other related characteristics of urbanity are speed, flows of people, information, and goods, and mobility, as well as concentration and density. Combined, these traits are sometimes seen as having pervasive effects, such as deviant behavior or alienation. Yet, the tenuous social bonds and anonymity often associated with urbanity in contrast to rurality are caused not so much by life in cities as by what Lefebvre calls technocratic control. Obsession with rational planning, rather than privileging the spontaneity and diversity of everyday life, has individualization and alienation effects.

URBANIZATION

Urbanization—the transformation of social life from rural to urban settings—is the seminal process in defining the course of civilization. Urban life evolved approximately ten thousand years ago as a result of sophisticated agricultural innovations that led to a food supply of sufficient magnitude to support both the cultivators and a new class of urban residents. These agricultural innovations, mainly irrigation-based public works, required a more complex social order than that of an agrarian village. Urbanization at its base is thus distinguished from the settled agrarian life that preceded it in two important respects: it embodies a multifaceted social hierarchy and relies on sophisticated technologies to support the activities of daily living (Childe 1936). These uniquely urban characteristics consistently define both urbanization and civilization from the past to the present.

Just as civilization emerged from urbanization in the past, so too does the future course of civilization hinge on our ability to incorporate the reality of contemporary urbanization into our responses to twenty-first-century challenges that include climate change, the elimination of severe poverty, ecological balance, the conquest of communicable diseases, and other pressing social and environmental problems. This is the case because since 2007 more than half of the world’s population resides in urban settings—a historic first.
Urban life can be defined, following Louis Wirth (1938), as life in permanent dense settlements with socially diverse populations. According to Lewis Mumford (1937), the city plays a critical role in the creation and maintenance of culture and civilization. Finally, following Henri Pirenne (1925), the crucial role of trade and production should be stressed. Thus urbanization involves an ongoing threefold process: (1) urbanization geographically and spatially spreads the number and density of permanent settlements; (2) settlements become comprised of populations that are socially and ethnically differentiated; and (3) these urban populations thrive through the production and exchange of a diverse array of manufactured and cultural products.

THE CONTEMPORARY SPREAD OF URBANIZATION

Although city life extends back at least ten millennia, the shape and size of modern urban settlements have roots that extend back only about 250 years to the Industrial Revolution, which marked a significant transformation in the role of cities as loci of critical productive activity and not just as cultural and political centers for a surrounding agrarian countryside. The present characterization of the world as predominantly urban is the cumulative result of this urbanization-industrialization trend. Industrial urbanization emerged first in the countries of the West, then in the countries of Latin America and the Caribbean, and is now strongly evident in Asia and Africa (Garau et al. 2005).

According to United Nations projections, by 2030 the increase of 2.06 billion in net global population will occur in urban areas. Over 94 percent of that urban total (1.96 billion) will be in the world’s less-developed regions (UN Population Division 2004). This means that virtually all of the additional needs of the world’s future population will have to be addressed in the urban areas of the poorest countries.

UN-Habitat, the United Nations agency responsible for promoting sustainable urban development, estimates that roughly one-third of the current urban population of about three billion live in places that can be characterized as slums. The UN classification schema for slums is a five-fold measure: lack of access to safe drinking water, lack of access to sanitation, inadequate shelter, overcrowding, and lack of security of tenure. If a place of residence meets any one of these measures, it is classified as a slum. By the year 2030, if nothing is done, the proportion of the urban population living in slums will rise to 43 percent (1.7 billion in an urban population of 3.93 billion). All of these people will be living in the urban slums of countries in the developing world, mainly in sub-Saharan Africa and Southeast Asia (UN-HABITAT and Global Urban Observatory 2003).

DENSITY, DIVERSITY, AND URBANIZATION

Urbanization is most powerfully observed through physical density (comparatively large numbers of people living in comparatively small areas). The ratio of population size to land area is the standard metric for evaluating density. It is a precise measurement that is not easily interpreted because neither the numerator (population size) nor the denominator (land area) is static. Political boundaries are only marginally helpful in defining the effective size of an urban settlement because at any moment changes in communications and transport technology alter the size of the relevant space over which urban residents live and work. Until the end of the eighteenth century, cities were spatially compact places with a radius of about one to two miles—the distance an individual could comfortably walk in carrying out daily activities. With the arrival of industrialization, effective urban size spread rapidly through the nineteenth and twentieth centuries. Contemporary urban or, more properly, metropolitan settlements easily encompass radii of 50 miles or more. This is a result of the continual improvement in rapid overland and even air travel modes and digital and wireless communications technology. The exact spatial configuration of any metropolitan settlement is a compromise between activities that must remain within walking distance and those for which residents are willing to travel (Schaeffer and Sclar 1980).

These spatially widening metropolises are not uniform in terms of their residential population densities. Hence density measurements alone tell us little about the quality of urban life. This quality can vary widely within the comparatively small confines of any metropolitan area. It is especially important to understand that high density per se is not an indicator of compromised living conditions. Metropolitan New York, which includes both the central city and the surrounding suburbs, has an average population density of over 5,300 people per square mile (ppm ²), but the wealthiest part of the region, Manhattan Island, has a density that exceeds 66,000 ppm ². By way of comparison Nairobi, Kenya, has a citywide density of over 1,400 ppm ², but its centrally located slum, Kibera, considered the largest in Africa, has an estimated population density of at least 100,000 ppm ². While Kibera’s density significantly exceeds Manhattan’s, the major determinant of the differences in quality of life relate to the quality of shelter and the ancillary urban services, such as water, sanitation, public safety, and most importantly transportation. Very poor urban residents must exchange life in high-density, poorly serviced places for the ability to walk to the places in the urban center where they earn a livelihood.

The major urban challenge of the twenty-first century concerns the ability of governments to effectively provide
adequate shelter and to plan and deliver services for metropolitan-wide areas in developing countries. The difficulty in meeting the challenge is rooted in part in the fact that the historical political boundaries of the central city and suburban (i.e., satellite city) subunits of government typically derive from an earlier century, before contemporary transport and communications technology redefined effective spatial relationships. The urban economies of modern metropolises now run beyond the legal jurisdictions of the subunits of government responsible for infrastructure and public services. The insistence of international financial agencies and donors on governmental decentralization in developing countries has only served to exacerbate this problem because it has left these governmental subunits with the responsibility but without either the technical ability or revenue sources. The result is that necessary regional planning and infrastructure investment to address the challenges of urbanization are often stymied.

Urban population growth is largely migration driven. On one side there is the push of rural poverty and on the other the pull of urban opportunity. This migration-driven growth is further exacerbated by natural rates of urban population increase (birth rates that exceed death rates). Social life in urban settlements is thus more complex than its village counterpart. The transactions of daily living in villages are governed by a social economy where goods and services are exchanged on the basis of social roles and rules of reciprocity rooted in longstanding customs and religious observances. The transactions of urbanization that confront the new arrivals are, in whole or in part, defined by the impersonal exchange relationships typical of a market economy. This transition is never a simple one-for-one exchange.

Because urban populations are continually in flux and often simultaneously expanding, they are often characterized by a multiplicity of informal and formal social relationships and institutions in a similar state of flux. The variations among an informal social economy and a formal market economy in any city at any moment in time are highly reflective of the larger external forces, such as globalization and migration, that are continually redefining the roles of different cities in a world of complex trading and production relationships. In the slum of Kibera, many of the activities of daily life, including the provision of vital public services such as water, sanitation, and public safety, are governed by an informal local, but powerful, social economy (Lowenthal 1975). In contrast, life in the working-class neighborhoods of cities in developed countries is typically an amalgam of informal social institutions imbedded in formal mechanisms of municipal public-service delivery. For the wealthiest residents of these same cities, virtually all the services they consume are provided via the formal institutions of government or market exchanges.

URBANISM AND THE GLOBAL ENVIRONMENT

Many of the patterns of contemporary urban development are extensions of those set in place in the nineteenth and twentieth centuries. These patterns were based on three assumptions: (1) energy was relatively inexpensive; (2) safe drinking water was abundant; and (3) the environment could absorb all the waste products of urbanization. None of these assumptions is any longer valid. Consequently, urbanization in the twenty-first century will have to be reconceived in both social and environmental terms. The world cannot afford the political instability and social costs of massive pockets of urban slum dwellers, nor can it accommodate urban growth through a further spatial spread that relies on urban transport powered by carbon-based energy sources and the discharge of waste products into both the local and global atmosphere. A healthy and vibrant environment is now a scarce but vital good.

Environmental problems are principally generated by the disorderly sprawl of urban settlements into the surrounding countryside. In the developed world, metropolitan areas organized around private automobile travel among low-density suburbs and tied to a central business district generate high volumes of automobile travel in the absence of tight land-use regulation and good public transport. This development pattern has led to increased mobile source pollution within the metropolitan areas and significant greenhouse gas emissions that endanger the whole planet. Sprawl requires an ever-increasing spread of impermeable (i.e., paved) ground surfaces. This in turn leads to the runoff of polluted waters into the groundwater supplies. The paved surfaces absorb heat from the sun and create urban heat islands that require more energy consumption and the emission of pollution and greenhouse gases to cool homes and offices. In addition, there are inadequate landfills to collect all the refuse of these high-consumption urban centers.

In the developing world, the problems are similar but more acute in their direct manifestation. The high rates of population growth lead to a pattern in which urban settlement runs ahead of infrastructure improvement. This leads to the establishment of informal settlements (i.e., slums) characterized by an absolute lack of safe drinking water and sanitation. The lack of adequate public transport and public health protection systems leads to a congestion of private cars and informal transports in the center of cities, which exacerbates the air quality problems and greenhouse gas emissions. The social costs of the lack of these services fall disproportionately on the poorest residents of these burgeoning metropolitan areas. These costs take the form of excessive mortality and morbidity rates, low rates of labor productivity, and the reinforcement of an ongoing trap of urban poverty.
Climate change generated by greenhouse gas emissions adds yet another layer of special urgency to these pressing social problems. It is the very concentrated nature of cities— their population densities and their centrality in social functioning—that makes them and their residents so vulnerable to the hazards and stresses that climate change is inducing. Rising sea levels and warming water make serious climatic assaults on cities more frequent. Devastating storms and floods that hit once in a century now occur in far shorter cycles. The impacts are not equally distributed. The poorest urban residents tend to live in the riskiest portions of the urban environments—flood plains, unstable slopes, river basins, and coastal areas.

Although the challenges of urbanization are formidable, the technical knowledge for their solutions exists. The question for the twenty-first century involves the ability of the international community, nations, and local governments to create institutions of urban planning and democratic governance that can effectively apply these solutions at a sufficiently broad scale that they can make a measurable difference.

URUGUAY ROUND

The Uruguay Round, which took place between September 20, 1986, and December 15, 1993, was the eighth round of multilateral trade negotiations conducted under the General Agreement on Tariffs and Trade (GATT). The “Final Act Embodying the Results of the Uruguay Round” was signed by 124 governments and the European Communities on March 15, 1994, at a ministerial conference in Marrakesh, Morocco. The act expanded the multilateral trade regime by establishing rules for the further liberalization of trade in goods, introducing new rules for services and intellectual property rights and establishing the World Trade Organization (WTO).

Prior to the Uruguay Round, seven rounds of multilateral trade negotiations that progressively lowered tariffs on goods were held between 1947 and 1979 under the auspices of the GATT, a provisional treaty. By the early 1980s, changing trade practices, increases in trade in services, the need for stronger intellectual property rights, and a growing membership of developed and developing countries made the weaknesses of the GATT apparent. A ministerial conference held in Geneva, Switzerland, from November 24 to 29, 1982, failed to launch a new round of trade negotiations as planned but initiated the process of agenda setting.

The Uruguay Round was launched at a ministerial conference held in Punta del Este, Uruguay, from September 15 to 20, 1986. The ambitious agenda included tariffs, nontariff barriers, agriculture, textiles, services, intellectual property rights, investment, and dispute settlement (see Table 1).

The Uruguay Round negotiations encountered significant delays, due in part to the political and economic sensitivity of the issues for developed and developing member governments. A ministerial conference held in Montreal, Canada, from December 5 to 9, 1988, was suspended after a deadlock developed between the United States and the European Communities over the liberalization of agriculture. Nonetheless, this meeting resulted in concessions on tropical products, revisions to dispute-settlement provisions, and the establishment of a trade policy review mechanism. The collapse of a ministerial conference held in Brussels, Belgium, from December 3 to 7, 1990, over the issue of agriculture jeopardized the Uruguay Round negotiations.

Following nearly a year of further technical preparations within the various working groups, GATT director-general Arthur Dunkel (1932–2005), a Swiss diplomat, tabled a draft of the “Final Act” on December 20, 1991. The draft was used as a basis for continuing the negotiations. The United States and the European Communities resolved their differences over agriculture with the Blair
House Accord of December 20, 1992. A meeting of the Quad (the trade ministers from the United States, the European Communities, Canada, and Japan) resulted in an agreement on a critical market-access package on July 7, 1993. Progress continued under the leadership of the next GATT director-general, Irish diplomat Peter Sutherland. In early December 1993, the United States and the European Communities compromised on antidumping measures and “agreed to disagree” for the time being on their remaining differences on audiovisual, financial, and shipping services, as well as subsidies. On December 15, 1993, although minor issues remained to be finalized, the member governments of the GATT agreed to conclude the Uruguay Round negotiations.

Following the ratification of the Uruguay Round agreements, a permanent WTO was established on January 1, 1995. The organization incorporated stronger dispute-settlement procedures and regular trade policy reviews of its members. The WTO governs the implementation of revised GATT multilateral rules on goods, including agricultural goods, and new rules covering services and intellectual property rights; manages the work program as outlined in some of the Uruguay Round agreements; and serves as a forum for multilateral trade negotiations.

U.S. CIVIL WAR

The Civil War (1861–1865) broke out in the early hours of April 12, 1861, when Confederate cannons opened fire on Fort Sumter in South Carolina's Charleston Harbor. The battle over the fort, which had become a symbol for both North and South, was both an end and a beginning. The assault marked the conclusion of years of spiraling hostility and suspicions between the North and South and of a series of escalating political, legal, and even physical altercations over the question of slavery. Slavery had been a point of contention since the inception of the United States, with the founders arguing over it in the debates over both the Declaration of Independence and the Constitution. In the interest of building the nation, however, they agreed to compromises that left the question of what to do about slavery to another generation. From that point until the 1840s, the matter stood, simmering, on the back burner.

REASONS FOR THE CIVIL WAR

The Mexican War gave the subject new urgency. Defeated, Mexico in 1848 ceded half a million square miles of territory to the United States (including the present-day states of California, Nevada, and Utah; most of New Mexico and Arizona; and parts of Colorado, Oklahoma, and Wyoming). Now the nation would have to decide whether—or what parts of—this new territory would be free or slave. Aside from the abolitionists, who were considered a radical fringe group, few people in the North disputed slavery in the states where it already existed because the Constitution protected the peculiar institution there. Congress, however, had the power to dictate whether the territories would be free or slave.

Thus the 1850s became a time of increasing hostility and suspicion between North and South as the nation wrestled with the issue of slavery in the territories. A new party, the Republicans, formed on the platform of opposing the expansion of slavery into the territories. By the time Abraham Lincoln won the presidency in 1860, the sectional divisions had grown so great that many Southerners refused to believe the president-elect when he said that he was interested in eliminating slavery only in the territories. Seven Southern states seceded in the months after Lincoln's election and declared themselves the Confederate States of America. Four more would leave the Union and complete the Confederacy after the attack on Fort Sumter.

Over the years, historians have blamed a number of forces for secession—including the industrializing North versus the rural South, cultural differences between the sections, and myopic and self-serving political leadership—but since the 1960s most historians have come to

| Fifteen negotiating sectors of the Uruguay Round. |
|-----------------|-----------------|-----------------|
| tariffs | services | dispute-settlement provisions |
| nontariff measures | intellectual property rights | GATT system |
| agriculture | investment measures | GATT articles |
| tropical products | natural resource protection | antidumping measures |

U.S. Civil War

agree that while those factors may have contributed to secession, the fundamental cause was slavery.

BLOODY BATTLES
After the attack on Fort Sumter, people on both sides of the Mason-Dixon line enthusiastically greeted the news of war. The common belief on both sides was that this would be a 90-day war. The first notable battle came July 21, 1861, at Manassas, Virginia, about 20 miles west of Washington, D.C. The battle was a Confederate rout that sent picnicking observers from the capital and green Union troops alike flying back to Washington. This loss would haunt most of the upper command of the Army of the Potomac for the rest of the war, imbuing them with a defeatist attitude that only Ulysses S. Grant was able to shake in 1864.

General Grant first came to the fore in early 1862 with major wins at Forts Henry and Donelson in Tennessee. His victory at Shiloh, Tennessee, in April was the first harbinger of how costly the war was going to be, however. After nearly losing the field on April 6, Grant battled back the next day. Casualties (killed, wounded, missing, and captured) on both sides approached 24,000. The toll was the highest in the history of the hemisphere, but by the end of the war Shiloh would rank as only the seventh bloodiest battle.

Robert E. Lee was appointed commander of the Virginia forces in June 1862 after General Joseph E. Johnston was seriously wounded at the Battle of Seven Pines. Lee quickly took control of what he now called the Army of Northern Virginia and unleashed it on the Army of the Potomac in the Seven Days’ Battles. Two months later he again scored a searing victory against the Northerners at a second encounter at Manassas (also known as Second Bull Run). From there, Lee began to move into Maryland. He saw this as an opportunity to pull the occupying enemy out of Virginia and to allow his hungry troops to live off the Northern countryside. He clashed again with the Yankees on September 17 at Antietam, a ferocious battle that remains the single bloodiest day in American history, with about 23,000 casualties.

Antietam was a draw, but Lincoln claimed it as a victory—one that gave him an opportunity to issue the preliminary Emancipation Proclamation that had been sitting in his desk drawer since July. For the first year of the war, Lincoln believed the South held a significant advantage. He quickly took control of what he now called the Army of Northern Virginia and unleashed it on the Army of the Potomac in the Seven Days’ Battles. Two months later he again scored a searing victory against the Northerners at a second encounter at Manassas (also known as Second Bull Run). From there, Lee began to move into Maryland. He saw this as an opportunity to pull the occupying enemy out of Virginia and to allow his hungry troops to live off the Northern countryside. He clashed again with the Yankees on September 17 at Antietam, a ferocious battle that remains the single bloodiest day in American history, with about 23,000 casualties.

Antietam was a draw, but Lincoln claimed it as a victory—one that gave him an opportunity to issue the preliminary Emancipation Proclamation that had been sitting in his desk drawer since July. For the first year of the war, Lincoln believed the South held a significant number of Unionists who would rise up against the government of Confederate president Jefferson Davis. As the war proceeded, however, Lincoln learned he was wrong. Unwilling to abolish slavery early in the war, Lincoln came to see emancipation as a way to strike at the heart of the Confederacy: Freedom for the slaves would deprive the South of its labor force and give the North an additional pool from which to draw soldiers and laborers for its own armies. Moreover, emancipation promised to keep the European powers, France and England, from formally recognizing the Confederacy and therefore kept them out of the war. It is impossible to know how European intervention might have affected the war’s outcome, but the assistance the French provided the Patriots during the American Revolution suggests that neutrality in this war was an important development in favor of the North. The Emancipation Proclamation, issued as a war measure, went into effect January 1, 1863. Slavery would be permanently abolished in 1865 with the ratification of the Thirteenth Amendment.

The winter of 1862–1863 was a dismal one for the Union. Lee crushed the Yankees at Fredericksburg in December. A month later the Army of the Potomac tried to move around Lee but got stuck in the mud and had to turn back. Grant’s efforts to gain Vicksburg, Mississippi, “the Gibraltar of the West,” were fruitless. The one bright spot for the Union was the Battle of Stones River, at Murfreesboro, Tennessee, over the New Year’s holiday.

Lee had more in store for the bluecoats. In early May 1863, he staged his most audacious victory, at Chancellorsville, Virginia, defeating a Union army nearly twice the size of his own. This success came with tremendous cost for the rebels, however. After a night reconnaissance, General Thomas “Stonewall” Jackson—more beloved in the South even than Lee at that time—was shot by his own jittery troops as he approached his lines. He died eight days later.

TIDE TURNS AGAINST CONFEDERATES
Lee took advantage of his win at Chancellorsville to move into the North again, this time into Pennsylvania. This again would be a chance to move the Union army out of Virginia and allow his own men to forage off the North’s bounty. It is not known where Lee intended to go, but when an advance column on July 1 bumped into Union cavalry on the west side of Gettysburg, Lee decided to fight. His decision on the third day of the battle to send thousands of men across about 1,300 yards of open ground against an entrenched enemy was suicidal. In fifty minutes, Lee suffered about 50 percent casualties, including three brigadier generals (James L. Kemper, Lewis A. Armistead, and Richard B. Garnett). Major General Isaac R. Trimble was badly wounded and had his leg amputated. The three days of battle would be the most costly of the war, claiming 51,000 casualties, and Lee, who favored offensive warfare, would spend the rest of the war on defense.

More bad news came for the Confederacy. On July 4, the day after Gettysburg ended, Grant finally succeeded in
taking Vicksburg. Now the Mississippi River was entirely open to the Federals, and the Confederacy was cut in half.

Grant had emerged as the North’s long-sought hero general, and when Lincoln promoted him to command all the armies in March 1864, many in the war-weary North thought that victory was certain and would come soon. They were wrong. Grant went on the attack, engaging Lee in a series of bloody battles in the spring of 1864, losing 64,000 men in six weeks. The fighting came to a halt at Petersburg, Virginia, where the two sides settled in for a siege that would last nine months.

Public sentiment turned on Grant and soured on Lincoln, too, as General William T. Sherman stalled outside of Atlanta and General Nathaniel Banks was turned back from an effort to move into Texas. Many people in the North were “wild for peace,” as one Republican politico said. Lincoln would not accept peace without the dual conditions of reunion and emancipation. Davis had just one requirement: independence. The two leaders were at loggerheads.

In the South, food shortages had plagued the Confederacy since 1862, and people at home began to starve the following year. Desertion became a problem for the Southern armies as men drifted home to help their families. By the summer of 1864, when Lincoln’s political fortunes tanked, many Southerners pinned their hopes for victory less on their armies’ winning than on Lincoln losing in the fall elections.

BEGINNING OF THE END

Like many others in the North—Republicans and Democrats—Lincoln was certain his bid for re-election would fail. Buoyant Democrats met at the end of August, pronounced the war a failure, and called for an immediate cessation of hostilities. But two days after the convention ended, Sherman took Atlanta, and Northerners were suddenly convinced the war was nearly won. Riding the tide of good feeling, Lincoln won by a landslide.

Just after the election, Sherman set out on his march across Georgia. His goal was to destroy the Southern civilians’ continuing will to wage war. Moving to Savannah in a 60-mile-wide swath, he succeeded. Meanwhile, the rebel army that had been in Atlanta moved toward Nashville, hoping to draw Sherman north. The effort failed disastrously when the Federals decimated the army on November 30 at Franklin, Tennessee. From this point on, Lee’s was the only viable army remaining in the Confederacy.

From Savannah, Sherman turned north in January 1865 and began a devastating march through South Carolina. Union soldiers unleashed their wrath on the people they held responsible for starting the war. Sherman continued to move north, ultimately intending to hook up with Grant and squeeze Lee in a pincer movement. Grant, meanwhile, was busy cutting all of Lee’s supply lines. On April 2, Lee decided to move to the west. Deprived of its military protection, Richmond, the capital, quickly fell.

With Grant in pursuit, Lee’s starving, ragged, and depleted army headed southwest. The chase lasted a week, until Grant cut Lee off at Appomattox Court House. There the two men signed a surrender that for all practical purposes ended the war that had claimed 620,000 lives (although fighting would go on for several weeks thereafter in other theaters). Clearly, Union victory was not inevitable. Lincoln’s tenacious commitment to victory, even if it cost him the presidency, was a key factor in the North’s success. Another critical factor was the willingness of generals such as Sherman, Phil Sheridan, and especially Grant to press the war ruthlessly on Confederate armies and civilians, even—in Grant’s case—at the cost of their own men’s lives. While one cannot discount the industrial, financial, and manpower advantages the North had over the South, ultimately the men in blue defeated the men in gray.

The last casualty of the war was Lincoln, who was shot in a theater on April 14—Good Friday—by John Wilkes Booth, an actor and Confederate sympathizer. Lincoln died the next morning. Standing at his bedside, his secretary of war said, “Now he belongs to the ages.”

USER COST

User cost refers to the expenses borne by the owner or renter of a capital asset resulting from the use of the asset for a given period of time. The user cost of capital also is sometimes referred to as the “implicit rental price” or the
“price of capital services.” A capital asset in theory can be any asset that is long-lived, which typically means it has a service life of more than one year. Durable goods such as machinery, factories, automobiles, computers, and even houses are examples of “tangible” capital assets. There are also “intangible” capital assets such as a business’s technological knowledge base built up by past research and development (R&D) activity or the value of its brand(s) built up by past marketing efforts.

Along with labor input, the service flows from capital assets are used by businesses to generate revenue. For many applications in economic research, such as measuring “multifactor” productivity or evaluating the potential effect on investment of changes in tax policy, one needs to measure the prices of capital and labor services. For labor, measuring this price is easy: It is simply the wage. For capital, though, measuring the price of a unit of service, that is, the user cost, can be much more complicated. If the firm leases a car for a year, for example, then, as with “renting” labor, the user cost is simply the rental price. This rent compensates the car’s owner for “wear and tear” (depreciation) inflicted on the car over the year, taxes on the rental income, the decline in its market (e.g., “blue book”) value over the year, and the foregone interest the owner could have earned if she had instead sold the car and invested those funds. Most capital assets used by a firm, however, are owned by the firm. Nonetheless, one can think of the firm as renting these assets to itself at an “implicit” rental price, equal to what the firm would get if it rented these assets out to other firms. In fact, government statistical agencies and others attempting to measure the user costs of specific capital assets often measure them by the prices observed in rental markets.

Most types of capital, however, do not have active rental markets. In these cases, the user cost is often measured by appealing to the neoclassical model and the seminal work of Robert Hall and Dale Jorgenson (1967). Hall and Jorgenson derived the formula for the user cost based on the neoclassical model’s proposition that the price of a capital asset should be equal to the present value of the rental income stream generated by the asset net of taxes and depreciation. From this equation, one can solve for the rental income per period, that is, the user cost, as a function of the price of the capital asset, the expected change in its price over the period, the interest rate, the depreciation rate, and taxes. Because these values are either known or can be estimated reasonably well, the user cost can be calculated using this formula.

It should be noted that this neoclassical concept of user cost is distinct from Keynes’s concept of user cost, which, roughly speaking, is the total cost to a firm of using capital in production (whereas the neoclassical user cost can be thought of as the price of a unit of services from that capital). The Keynesian user cost captures the value of capital that is “used up” or “consumed” in the production process. In Keynes’s production framework, the sum of labor (“factor”) cost and user cost equals the total (“prime”) cost of production (see chapter 6, Keynes 1936).

UTILITARIANISM

Utilitarianism is an intellectual movement in the social sciences and in philosophy. It is founded on the principle that individual actions, as well as laws, economic decisions, and social policies should promote the “greatest happiness.” Jeremy Bentham (1748–1832), an English legal theorist and political reformer, first outlined the utilitarian theory in his Introduction to the Principles of Morals and Legislation (1789). Human beings are governed, according to Bentham, by “two sovereign masters, pain and pleasure.” Actions are to be judged by their utility—that is, by a “felicific calculus,” or reckoning of the benefits and harms they produce. Bentham held that such a calculus must take into account the number of persons whose interests are affected, as well as the intensity, duration, and degree of certainty of the expected pleasure or pain. In addition, one should take into account the nearness or remoteness in time, as well as the likelihood that an initial pleasure will be followed by pain, or a pain by pleasure. Whether an action or the adoption of a social policy is judged to be “good” or “bad” depends on the result of this calculation.

Bentham built on the work of thinkers such as John Locke (1632–1704), Claude-Adrien Helvétius (1715–1771), and Adam Smith (1723–1790), and himself became the center of a group of intellectuals and social reformers that included James Mill (1773–1836), William Godwin (1756–1836), and the economists David Ricardo (1722–1823) and Thomas Malthus (1776–1834). On the
grounds of social benefit, "radical" utilitarian reformers called for changes to the laws governing parliamentary elections, the prison system, treatment of the poor, and other matters. Early utilitarians aimed at abolishing unnecessary suffering and promoting individual happiness through the rational study of the long-term consequences of policies and actions. For example, they believed it necessary to control the procreative impulses that can lead to rampant population growth. Because of their unsentimental approach to questions of moral and social life, utilitarians gained a popular reputation as lacking spontaneity, emotion, and artistic sensitivity. Charles Dickens’s *Hard Times* (1854) includes a memorable portrayal of utilitarianism in the character of Thomas Gradgrind, whose insistence on educating his children only in "facts" rather than "fancy" (imagination) leads to unhappiness for all concerned.

John Stuart Mill (1806–1873) was the son of Bentham’s associate James Mill. J. S. Mill’s early education was based on Benthamite principles, and in his *Autobiography* (1873) he criticized his upbringing for its overemphasis on developing the analytic powers at the expense of educating the emotions. Despite these reservations about his own education, Mill adopted utilitarian principles and became the movement’s most articulate spokesperson, developing the theory in works such as the *Principles of Political Economy* (1848). In *On Liberty* (1859) Mill defended the importance of individual freedom of thought and action, arguing that the individual is the best judge of his or her own good and that society benefits from the experimentation that occurs in an atmosphere of liberty. In *Utilitarianism* (1863) he went beyond Bentham’s famous statement in *The Rationale of Reward* (1825) that “Prejudice apart, the game of push-pin is of equal value with the arts and sciences of music and poetry. If the game of push-pin furnish more pleasure, it is more valuable than either” (p. 253). In contrast to Bentham, Mill argued that there are qualitative differences among pleasures that affect their value. In *The Subjection of Women* (1869) Mill evidenced the radical bent of utilitarianism, challenging deeply held prejudices against women’s capacity for intellectual development and self-governance. He argued that it is impossible to know whether women are innately less capable than men without giving women the same educational opportunities that men have.

Among the well-known later defenders of utilitarian philosophy were the English philosophers Henry Sidgwick (1838–1900) and George Edward Moore (1873–1958). In the late twentieth century utilitarian ethics was further developed by philosophers including J. J. C. Smart (b. 1920) and Peter Singer (b. 1946). Singer’s contributions include highlighting the utilitarian concern for the interests of nonhuman animals. He used the term *speciesism* to refer to the view (which he opposes) that nonhuman animals deserve less consideration than human beings solely on the basis of species membership.

**VARIETIES OF UTILITARIANISM**

Utilitarianism is still the most prominent form of *consequentialism*, the view that actions should be morally judged on the basis of their good or bad results, rather than on their intrinsic rightness or wrongness. Within utilitarianism, different schools of thought have arisen in response to debates over the implications of the basic theory. *Act utilitarians* argue that each individual action should be judged by its beneficial or harmful results, so, for example, it may be morally permissible or even morally necessary to tell a lie in order to save an innocent life. *Rule utilitarians*, in contrast, evaluate not individual actions but social rules or types of actions. For a rule utilitarian, because telling lies generally results in more harm than benefit, lying is generally prohibited. In addition to the act versus rule debate, utilitarians have disagreed over whether utilitarianism is based on an empirical description of human motivation or a vision of how individuals ought to be motivated, and also over the question of how far the interests of individuals and those of social groups can and should be harmonized. The various versions of utilitarianism agree, however, on the need for impartial and equal consideration of the interests of all those affected by any decision.

**OBJECTIONS TO UTILITARIANISM**

Utilitarianism has met with numerous objections. First, some object that utilitarianism is unconcerned with how benefits and harms are to be distributed, as long as the maximum amount of total satisfaction is achieved and as long as no individual’s interests are weighed more heavily than anyone else’s. Utilitarianism seems more concerned with how the aggregate of individuals fares, even if a minority must suffer undeservedly in order to provide satisfaction to the majority. A related criticism was made by economist Amartya Sen in *On Economic Inequality* (1973). Sen argued that, despite the fact that utilitarianism is often believed to lead to economic egalitarianism, or an equal distribution of income, under certain circumstances it leads to just the opposite. If person A, for example, derives greater utility than person B from the same amount of income (perhaps because person B suffers from a chronic illness or a disability and person A does not), utilitarianism seems to lead to the paradoxical conclusion that person A should be given more resources than person B, in order to increase the amount of utility of the group as a whole. It is because utilitarianism concerns itself with the good of the aggregate, also known as sum-ranking, that it leads to paradoxical results in this and similar cases.
Utility Function

The utilitarian commitment to equal consideration of individuals’ interests thus appears to be in tension with its practice of judging the goodness of a particular situation by measuring the aggregate of individual utilities.

A second objection is that utilitarians make ethical decisions based on the satisfaction of human preferences. Preferences are notoriously subjective and malleable, and they differ according to the circumstances to which individuals are accustomed. For example, someone who is used to great wealth may experience a sense of deprivation under circumstances that would seem acceptable or even luxurious to someone accustomed to severe poverty. Moreover, because preferences are of many different types, it may not be possible or appropriate to treat them as commensurable (measurable by a single standard). For example, it may not be possible to weigh the happiness gained from friendship against the happiness gained from having good health. Third, some object that utilitarianism demands excessive sacrifices from its adherents. For example, it appears that in order to bring about the greatest happiness for all people, those who are relatively well-off would be obliged to sacrifice their own material well-being, and that of their dependents, to the point at which they attain a level of satisfaction equal to that of the least well-off person who could be assisted by such a sacrifice. A fourth objection is that utilitarianism allows or even requires the performance of certain actions that are ordinarily considered unethical, such as breaking a promise, making a false accusation, or even killing an innocent person, if that action could bring about a benefit sufficiently great to outweigh its harmful effects.

Despite these and other criticisms, utilitarianism continues to exert an influence on ethics and social policy. Whenever a cost-benefit analysis is performed in order to assess the worth of a particular course of action, utilitarian thinking is at work. The appeal of utilitarianism lies in its affirmation of individual equality and its view that the goal of both personal ethics and public policy is to bring about a preponderance of benefit over harm to all who are affected by human actions.

UTILITY FUNCTION

“Economics is the science which studies human behavior as a relationship between given ends and scarce means which have alternative uses.” This definition of economics, stated by Lionel Robbins in his landmark work An Essay on the Nature and Significance of Economic Science (1932), established the fundamental nature of economics. Given a population with seemingly unlimited wants and needs, the questions of how goods and services are consumed, produced, and distributed are the primary ones to be answered. As a consequence, the amount of satisfaction or happiness derived from consuming resources is of particular interest. Are goods and services being distributed and consumed so as to provide the greatest amount of happiness to individuals and society as a whole? To address this problem, economists require some way of measuring the happiness that is attained from consumption. Utility can be defined as the amount of usefulness or satisfaction or happiness gained by consuming goods and services. Utility is dependent on the bundles of goods consumed by an individual, with greater quantities of goods representing greater levels of happiness or utility. Thus, we can define a utility function as a positive relationship between the consumption of goods and services and the amount of utility received from that consumption. If a utility function can be clearly defined, then it is possible to address the question of maximizing an individual’s utility, based on the size of their consumption bundle. Comparisons can also be made between different bundles, and we can make conclusions regarding individual’s preferences, based on their ranking of various bundles. A well-defined utility function is also relevant when considering the welfare of an entire society. It enables social planners to determine how to distribute goods to individuals so as to maximize the total utility of a society.

The concept of utility and the doctrine of utilitarianism are rooted in Jeremy Bentham’s Principles of Morals and Legislation (1789). In that work’s introduction, Bentham declares that humans are placed “under the governance of two sovereign masters, pain and pleasure” and that the “principle of utility recognizes this subjection, and assumes it for the foundation of that system, the
object of which is to rear the fabric of felicity by the hands of reason and of law” (p. 1). Bentham’s “felicific calculus” was an attempt to construct a measure of utility, based on the following dimensions of pleasure and pain: intensity, duration, certainty or uncertainty, and propinquity or remoteness. The difficulties associated with such measurements were enormous, however. There was no clear way to compare feelings that were qualitatively unlike each other, nor any way to measure the intensity of feelings, much less make any comparison between the feelings of different individuals. Nonetheless, by the 1870s utility theory had come to be widely accepted, due to the independent contributions of William Jevons, Carl Menger, and Léon Walras, the leaders of the so-called Marginalist Revolution. Their works initiated a movement away from the classical theory of value set forth by Adam Smith and David Ricardo, among others, which held that the value of a product was based on its production costs. Following Jevons, Menger, and Walras, the emphasis came to be placed on the perceived value of a good and the utility a consumer would receive from the consumption of the good. The existence of utility was accepted by all three; however, the problem of the measurability of utility and the issue of defining the exact form of the utility function remained. None of the three explicitly addressed the problem of measurability; they either merely assumed the existence of such measurements, or stated that utility was measurable but not at the present time.

There were, however, attempts to develop the utility function, which is based on the quantities of the goods consumed. For the goods \( x_1, x_2, x_3, \ldots \) an individual’s utility was written as a function of those goods that represented ordinal utility: \( \varphi (x_1, x_2, x_3, \ldots) \). This generalized form was proposed by Vilfredo Pareto, who called it an index function, and then also later on by Francis Edgeworth. Greater levels of consumption were believed to provide greater levels of utility. Consumers were assumed to have rationally ordered preferences and to choose a consumption bundle so as to maximize utility. Utility was also assumed to diminish with each additional unit consumed of each good. Additional units consumed of a good will increase an individual’s total utility, but at a diminishing rate. In the works of several economists, including William Lloyd, N. W. Senior, and Richard Jennings, clear statements of diminishing marginal utility were given. By using the concept of diminishing marginal utility, Adam Smith’s water/diamonds paradox—water is necessary for life and diamonds are not, but the price of diamonds is many times higher—could now be resolved. The relative abundance of water versus the relative scarcity of diamonds is the key here, along with the marginal utility of the last unit consumed of each good. Water is abundant enough that the marginal utility obtained from the last gallon consumed is rather low, compared to the marginal utility of the last diamond consumed.

The concept of diminishing marginal utility led in turn to the concept of the downward sloping demand curve. Walras successfully established the link between utility and demand, by using equations expressing maximum satisfaction for an individual. For some given number of \( m \) commodities, he derived the demand function as a relationship between the quantity and price of a commodity and the prices of all the other commodities, \( \text{ceteris paribus} \)—that is, with all other variables (such as money income and tastes) held constant. In 1892 Pareto rigorously showed that diminishing marginal utility directly implied negatively sloped demand curves. Alfred Marshall’s Principles of Economics, first published in 1890, also formally constructed a demand curve based on utility and marginal utility. Marshall stated that “[t]here is then one law and only one law which is common to all demand schedules[,] … that the greater the amount to be sold, the smaller will be the price at which it will find purchasers” (pp. 159–160)—a conclusion he drew from the concept of diminishing marginal utility. Eugen Slutsky and John Hicks, both working with the assumptions that the utility function was additive and that consumers faced the diminishing marginal utility of consumption, also derived the downward sloping demand curve. The total change in demand for a good could be decomposed into two elements: the substitution effect and the income effect. For instance, if the price of a good increases the substitution effect dictates that a consumer will substitute consumption for a cheaper good in place of the now more expensive good. The income effect dictates that due to the price increase, a consumer effectively has less real income to spend, and will therefore consume less of both goods. For a normal good, this means that a price increase will mean a decrease in quantity demanded, and thus the demand curve will be downward sloping.

Another important extension of the utility function is the indifference curve, devised initially by Edgeworth. Consider a case involving two goods, and the levels of utility gained from consuming various combinations of the goods. A three-dimensional graph of this function, with two coordinates representing quantities of the two goods, and the third coordinate representing utility level, will give a utility surface, which rises with increasing quantities of the two goods consumed. For varying levels of utility, an indifference curve can be represented by “slices” of the utility surface that are parallel to the plane of the two commodities. An indifference curve is a two-dimensional graph of all the possible combinations of two goods that will give a consumer a given amount of utility. The downward slope of an indifference curve indicates the rate of tradeoff between the two goods, known as the marginal rate of substitution. Because a consumer is assumed to
experience diminishing marginal utility for each additional unit consumed, decreasing consumption of one good must be offset by increasingly greater consumption of the other good, if the same level of utility is to be maintained. This fact gives rise to the shape of the indifference curve, which is convex to the origin. A graph of indifference curves for varying levels of utility is known as an indifference map. Consumers prefer to be on higher indifference curves, because these represent greater levels of consumption bundles and therefore greater levels of utility. Paul Samuelson's revealed preference theory was another area of work that described consumer behavior. Instead of assuming the existence of a utility function and establishing its properties, Samuelson stated that consumers revealed their preferences by what goods they purchased. From observing consumer behavior, preference relationships between bundles of goods could be established, and downward sloping indifference curves could be constructed, based on diminishing marginal utility associated with increasing consumption.

The advent of modern utility theory came with the publication of John von Neumann and Oskar Morgenstern's *Theory of Games and Economic Behavior* in 1947. In this work, it was established that individual agents make decisions so as to maximize the expected amount of utility they received from their choice of a consumption bundle. Because these choices are assigned probabilistic outcomes, utility theory could be considered to have a game theoretic framework that includes risk and an individual's attitudes toward risk-taking. Decisions regarding utility-maximization are influenced by the probabilities of outcomes. If a consumer's utility is assumed to be based on consumption as a whole and not just on one good, measures of risk aversion can be written in the form developed by economists Kenneth Arrow and John Pratt. Measurements of risk aversion are of particular importance in analyzing the behavior of consumers who make investment decisions under conditions of uncertainty.

In addition to examining economic activity as it is, without value judgment, the discipline of economics also attempts to establish normative guidelines, based on how things ought to be. Welfare economics considers the normative aspects of economic outcomes and analyzes whether these outcomes can be improved through benevolent social planning. Thus, the question of maximizing social utility becomes relevant. Edgeworth and Marshall, among others, assumed that utility was *cardinal*—that is, measurable in absolute terms—and that it was possible to make interpersonal comparisons of individual utility functions. This led to their conclusion that a social welfare function could be constructed based on a summing of all individual utility functions. Pareto, Hicks, and Nicholas Kaldor took a different approach, using an *ordinal utility*, which considers only the rankings of different bundles of goods. Social welfare was analyzed on the basis of Pareto efficiency, the principle that a society’s condition was optimal if no further improvements in the allocation of goods could be made without making someone worse off. Kaldor-Hicks efficiency was an extension of Pareto efficiency. In this model, an outcome could be improved if the individuals who would be made better off by a reallocation of goods compensated those who would be made worse off.

UTILITY, OBJECTIVE

Utility is value. Objective utility is nonrelative value. It may attach to a good for a person without being relative to the person’s attitudes. For example, a baby’s health has high objective utility although the baby is too young to value health.

Utilitarian moral theorists such as Jeremy Bentham ([1789] 1996) and John Stuart Mill ([1861] 2006) formulated accounts of objective utility. According to Bentham it is pleasure, and according to Mill it is happiness. Some contemporary utilitarians such as Fred Feldman (1986) accommodate pluralism about values. They recognize nonhedonistic basic values such as justice.

Objective utility contrasts with subjective utility. Subjective utility is a person’s rational strength of desire at any time. It varies from person to person because of differences in goals and information. John von Neumann and Oskar Morgenstern (1944) define subjective utility in terms of coherent preferences concerning gambles. Such preferences ground quantitative comparisons of a person’s attitudes toward the gambles’ possible outcomes.

The relation between objective utility and subjective utility is twofold. First, subjective utility is a component of objective utility. It is good that a person satisfy sensible desires. Second, a person should desire the good and have an aversion to the bad. If an event is good, then a person has a reason to desire its occurrence. Objective utility influences subjective utility.

Information and rationality make subjective utility respond to objective utility. Consider the role of information. A person’s desires depend on her information. Giving a person full information moves her subjective utility assignment closer to an objective utility assignment. Next, consider the role of rationality. Rationality regulates basic preferences and information’s generation of derived preferences. It imposes structural constraints such as consistency of preferences, procedural constraints such as the requirement to taste flavors before forming preferences among them, and substantive constraints such as the requirement to prefer happiness to unhappiness, other things being equal. An informed, rational, cognitively ideal agent whose basic goals are intrinsic goods has a subjective utility assignment that matches an objective utility assignment.

Fields such as welfare economics use objective utility to evaluate public policies. As W. Kip Viscusi (1998) explains, government regulatory agencies seek cost-effective means of reducing risks of injury and death. A good regulation increases objective utility by promoting the public’s interests rather than by catering to the public’s wishes. For example, consumers want labeling of genetically modified food. Nonetheless, the U.S. Food and Drug Administration does not require labeling because its benefits do not compensate for its costs. Objective utility guides regulation.

Applications of objective utility often use a function that assigns numbers to objects evaluated. The higher the number is, the more value the object has. In some cases numbers assigned represent only a ranking, but in other cases they represent quantitative comparisons. The value of saving two lives may not only be greater than but may also be twice as great as the value of saving one life.

Measures of objective utility vary. One measure uses contribution to realization of basic goods. Life is a basic good. Water is necessary for life. So water has high objective utility using this measure. Market-value is another measure of objective utility. That people want an object is a sign that it has value. Market-value may not indicate contribution to basic goods, however. Water has low market-value because it is plentiful. The labor invested in a product is a common measure of objective utility. According to this measure, a handwoven rug has more objective utility than a gold spoon if more labor went into its fabrication. These methods of measuring objective utility have limited ranges of application and yield only approximate results. To formulate an account of objective utility, Amartya Sen (1985) uses capabilities to function and Daniel Kahneman (2000) uses momentary pleasurable experiences.

According to some theorists, objective utility attaches to physical objects such as land. A parcel of land’s objective value depends on factors such as fertility. According to other theorists, objective utility attaches to realization of a proposition’s truth, that is, an event or a state of affairs. The objective utility of a person’s owning a parcel of land may replace the objective utility of the parcel of land.

Because the value of a peasant’s owning a parcel of land differs from the value of a land baron’s owning the same parcel, attributing objective utilities to states of affairs involving the land’s ownership makes objective utility sensitive to the variety of factors affecting value.

Value theory distinguishes intrinsic and extrinsic value, as Michael Zimmerman (2001) explains. An object with intrinsic value is good for its own sake. An object with extrinsic value is good because it leads to objects with intrinsic value. Intrinsic value is basic, and extrinsic value derives from intrinsic value. Traditional examples of intrinsic values are pleasure, justice, liberty, knowledge, beauty, and achievement. Traditional examples of extrinsic values are money, time, and power. A proposition’s realization has intrinsic value in virtue of features that the proposition’s realization entails rather than features its realization causes. Objective utility depends on both intrinsic and extrinsic value.

Being good for a person is not the same as being good according to a person. Health is good for a person even if he is indifferent to his health. Promoting a person’s interest, well-being, or welfare is good for the person. Some accounts of objective value claim that it rests exclusively
on value for sentient beings. Hedonism supports this view because all pleasure resides in a sentient being. Pluralism accommodates objective value that is independent of value for sentient beings. For example, social equality may have objective value without being good for any person.

A common criticism of objective utility is that non-relative value does not exist, or is unknowable. Persistent disagreements about values are grounds for this criticism. Another criticism is that some values are nonquantitative and incomparable so that a quantitative representation of all values is impossible. For example, one person’s delight in music may not be comparable to another person’s recovery from a cold. Then objective utility’s interpersonal comparisons of value lack a foundation. Objective utility, despite criticisms, maintains a role in moral theory and the social sciences.

BIBLIOGRAPHY

Utility, Subjective

In economic theory, subjective utility is the satisfaction a consumer perceives to have resulted from consuming a product. Subjective utility is usually referred to simply as “utility.” The early economists Jeremy Bentham and John Stuart Mill maintained that the goal of society is to maximize the total utility of its members. In the early twenty-first century economists refer to this as welfare maximization. Utility theory begins with assumptions as to individuals’ preferences. When a consumer is willing to trade off one product or product attribute for another (for example, less engine power in exchange for improved gas mileage), it is said that the person has compensatory preferences. When a consumer is unwilling to trade off one product or product attribute for another regardless of the quantity of the second product offered (for example, a family of six needs a car with six seats no matter what the other attributes of the car are), it is said that the person has non-compensatory preferences. Economists typically assume compensatory preferences because they are intuitively justifiable, are easier to represent mathematically, and reflect the vast majority of true preferences. Preferences are typically represented by utility functions, which map consumption to utility.

Utility can be regarded as ordinal or cardinal. Cardinal utility is a numeric measure of utility, where units of utility are called utils. Ordinal utility is an ordering of objects according to utility. For example, an ordinal utility function might show a consumer deriving more utility from apples versus oranges, while a cardinal utility function might show a consumer deriving 100 units of utility from apples versus 80 units from oranges. Thus while ordinal utility is more realistic than cardinal utility in that it is difficult to measure utility numerically, cardinal utility can describe differing strengths of preference that ordinal utility cannot. Economists who use cardinal utility to describe consumer preferences note that, while consumers do not actually measure utility numerically, consumers behave (in the aggregate) as if such a measure were possible.

While utility cannot be directly measured, it is possible to obtain indirect measures by determining how much money a person must be given to compensate that person for the loss of a unit of product. For example, in an experiment a subject who has not eaten breakfast and who knows he or she will not eat dinner is given three slices of pizza for lunch. The person is then offered successively greater amounts of money in exchange for giving up one slice of pizza. The minimum amount of money the subject is willing to accept in exchange for the pizza is the dollar equivalent of the utility the subject expects to obtain from the slice of pizza.

Central to consumer theory is the idea of declining marginal utility. Marginal utility is the additional utility a consumer obtains from consuming one more unit of a product. Marginal utility is assumed to decline as more units of a product are consumed. For example, to a hun-
The first slice of pizza eaten yields significant marginal utility. The second slice yields less marginal utility, because the person has already consumed one slice of pizza and is less hungry than he or she was prior to consuming the first slice. After consuming the second slice of pizza, the person's total utility is the marginal utility he or she received from the first slice plus the marginal utility he or she received from the second slice. The third slice of pizza yields less marginal utility than the second because the person is even less hungry than he or she was prior to the second slice. Eventually the person will have had enough slices of pizza that he or she does not want any more, even if the pizza is free. At this point the person's marginal utility has declined to zero (or may even be negative), consuming an additional slice of pizza will not increase the person's utility.

The phenomenon of declining marginal utility can be said to occur because consumers obtain utility from two sources: the good consumed and the variety the good represents. The level of variety measures how different the good is from other goods the consumer has consumed recently. For example, someone who is eating potato chips may stop eating not because he or she is full but because he or she is "tired" of potato chips and now seeks something different (like a soft drink). Without having had a drink, as the person eats more and more potato chips, the marginal utility of an additional potato chip falls because an additional potato chip is more and more like what the person has already consumed. Meanwhile the marginal utility of a soft drink rises because an additional soft drink is less and less like what the person has already consumed. Utility from variety explains why consumers tend to like to consume together things that are markedly different: beer and pizza, hot apple pie and cold ice cream, hot peppers in a sweet sauce.

If consumers can consume at no charge, they will seek out the goods that yield the greatest marginal utility. When consumers must pay for what they consume, they seek out the goods that yield the greatest marginal utility per dollar. This is the phenomenon that results in beer drinkers suddenly becoming scotch drinkers when the drinks are on the house. The consumer obtains greater marginal utility from a scotch than from a beer. But the difference in marginal utilities between the two drinks does not compensate for the difference in price between the two drinks. The consumer is said to attain the optimal consumption combination when the marginal utility per dollar for each of the goods the consumer is consuming is the same. For example, suppose a consumer obtains a marginal utility of 10 from 1 more cup of coffee and a marginal utility of 6 from 1 more bagel. If the bagel costs $2 and the cup of coffee costs $1, the consumer will purchase the bagel because the marginal utility per dollar for the bagel (6 / 1 = 6) is greater than that for the coffee (10 / 2 = 5). But having consumed the bagel, the consumer's marginal utility for another bagel falls to (for example) 4. Now the marginal utility per dollar for the bagel (4 / 1 = 4) is less than that for the coffee (10 / 2 = 5). So the consumer buys a cup of coffee. Whenever the marginal utility per dollar for one good exceeds that of another good, the consumer consumes more of that good.

In the extreme the consumer spreads his or her consumption dollars among many goods such that the marginal utility per dollar is the same for all the goods.

In the presence of uncertainty, consumers are said to maximize expected utility. Expected utility is the level of utility the consumer expects to obtain following resolution of the uncertainty. For example, suppose a person is offered a choice between $50 cash and a lottery ticket that carries a 50 percent chance to win $100 and a 50 percent chance to win nothing. The expected value of the lottery ticket is $50 ($50 = 0.5 × $100 + 0.5 × $0). The expected value of the lottery ticket is the same as the value of the cash. However, some consumers will choose the lottery ticket, while others will choose the cash. The consumers who choose the lottery ticket can be said to expect more utility from the lottery ticket than from the $50 cash. These consumers are called risk preferential or risk lovers because, apart from the utility they would receive from the money, they receive additional utility from the existence of uncertainty. More formally, the utility the risk preferential consumer expects to get from the lottery ticket exceeds the utility the consumer would get from what he or she expects to win. A risk preferential person will tend to seek out risks even when there is a negative expected return associated with the risk. Similarly a risk averse consumer is one who, apart from the utility he or she would receive from the money, receives disutility from the existence of uncertainty. A risk averse will tend to avoid risks even when there is a positive expected return associated with the risk. A risk neutral consumer is one who receives neither utility nor disutility from risk. A risk neutral person will neither seek out nor avoid risk for its own sake but will consider only the expected return associated with the risk. If the expected return is positive, the risk neutral person will undertake the risk. If the expected return is negative, the risk neutral person will avoid the risk.

Evidence suggests that people's attitudes toward risk change depending on the size of the uncertainty relative to their wealth and whether the uncertainty involves gains or losses. On average, the less a person's wealth, the more risk preferential the person tends to be. Also people tend to be more risk preferential with respect to potential gains but risk averse with respect to potential losses. Hence, the same person may both play the lottery (an activity that increases risk but involves potential gain) and purchase...
insurance (an activity that decreases risk but involves a reduction in potential loss).

UTILITY, VON NEUMANN-MORGENSTERN

Von Neumann–Morgenstern utility considers decision making under risk. It concerns choice when the probabilities of the possible outcomes of that choice are objectively known. This decision framework differs from decision making under certainty and decision making when probability is subjective. John von Neumann and Oskar Morgenstern (1947) follow a behavioral framework analogous to the revealed preference framework developed by Paul A. Samuelson (1938 and 1947). Quasi-operational experiments are envisioned where people’s behavior is held to satisfy key behavioral axioms.

The formal treatment of expected utility began with Daniel Bernoulli (1738) in his formulation of the St. Petersburg Paradox. In this paradox, a game is considered that has an infinite expected value. The paradox is that people will not pay a large sum to play this game. The game is one in which a fair coin (equal probability of a heads or tails) is tossed. If a head occurs the coin is tossed again and again until a tail occurs. Once a tail occurs the game is over. The payoff from playing the game depends on the number of consecutive heads that occurs. The pay off for $H$ heads is defined as $2^H$. That is, if one head occurs, $2$ is paid; if two heads occur, $2 + 4 = 6$ is paid; and so forth. The probability of at least one head is $1/2$, the probability of at least two consecutive heads is $1/4$, and so forth. Consequently, the expected value of the game is

$$\sum_{i=1}^{\infty} 2^i \cdot \left(1 - 2^{-i}\right) = \sum_{i=1}^{\infty} \left(1 - 2^{-i}\right) = \infty.$$

Despite the infinite expected payoff, few would pay large sums to play this game. Bernoulli provided an answer to this paradox in terms of diminishing marginal utility. He argued that it is the utility of the gains and not the monetary gains from the game that are relevant to the person’s decision whether or not to play the game. With diminishing marginal utility, the gains from the game could be finite and small.

Von Neumann–Morgenstern utility can be illustrated by considering lotteries with two possible prizes, $A$ and $B$, and a cost for playing the lottery, $Y$, with $A < Y < B$. Let $P$ be the probability of the most favorable prize, $B$, and $(1 - P)$ be the probability of the less favorable prize, $A$. Six key assumptions (Luce and Raiffa 1957) will assure that a utility function can be defined from the revealed preferences of players. These assumptions assure that a probability can be found for every lottery where the decision maker is indifferent between the price of the lottery ticket and the lottery. In other words,

$$U(Y) = (1 - P)U(A) + PU(B), \text{ or } U(Y) = U(A) + (U(B) - U(A))P.$$

Suppose we rank every possible outcome of any lottery from $W$, the worst possible, to $B$, the best possible and assign an ordinal number to $U(W)$ and $U(B)$ representing this ranking. Then $U(Y)$ for any $Y$ can be found as a linear transformation of these two extreme outcomes. Hence, Von Neumann–Morgenstern utility is cardinal but only because it represents a linear transformation of the probabilities in the lotteries. It is not cardinal utility in any other context.

**UTOPIANISM**

Utopianism refers simultaneously to social issues and to questions of the imagination. In fact, utopianism can be seen in action anytime the imagination is put to the use of remaking social life. The term describes a tendency to think of the world as a place to be made more perfect. The utopian impulse in history can be understood as posing the question of how else humans might organize themselves. It is generally agreed that the first utopian society in Western thought is to be found in Plato’s *Republic* (c. 400 BCE), a realm where philosophers-kings govern. The term *utopia* was coined by Sir Thomas More (1478–1535) in *Utopia*, first published in 1516. The writing of More’s *Utopia* corresponds to the period of discovery by Europeans of what was called the New World, with all that it ushered in to Europe’s political economies and social imagination.

Ambiguous from the outset, the term *utopia* could be read as a joining of the Greek prefix *eu* with the word *topos* (place), which would translate as “no place.” The first syllable could equally be understood as the Greek prefix *eu*, rendering utopia the “good place.” Later writers, notably William Morris (1834–1896) in England, who titled his utopian fiction *News from Nowhere* (1891), recognized that the improved society they envisioned is, in principle, impossible to find or perhaps even to construct. However, this problem has never stopped utopian thinkers from casting their visions in print and in fact. Utopian societies or communities, though usually short-lived, have been founded in countries across the globe, especially in times of revolutionary change. And utopian manifestos and programs have been written and promulgated in such times as well.

Whether cast as prelapsarian or millenarian, the tense of the utopian narrative is inevitably the future and the mood is subjunctive, as utopians speculate about what may come to be. Even Edward Bellamy’s (1850–1898) *Looking Backward* (1888), the most popular late nineteenth-century utopian novel, describes the imaginary future through a fictionalized past. Throughout the nineteenth century, utopian movements arose that looked forward to how lives might be improved by the Industrial Revolution. Other such movements looked backward with nostalgia for ways of life that had been lost due to the same irrevocable changes. Labor was no longer primarily agricultural but industrial, and cities were rapidly growing, making the lost pastoral a focus of cultural longing. By the mid-twentieth century, such impulses toward the “good place” had been brought up short by world events, leading to a period of dystopian thinking. Two key texts representing this perspective are *Brave New World* (1932) by Aldous Huxley (1894–1963) and *1984* (1949) by George Orwell (1903–1950).

A strategic moment in the history of utopianism is the shift from early nineteenth-century thinkers such as Charles Fourier (1772–1837) in France and Robert Owen (1771–1858) in England, who proposed a form of utopian socialism, to the writings of Karl Marx (1818–1883) and Friedrich Engels (1820–1895), who differentiated their ideas as scientific socialism. This conceptual divide leads some to see utopianism as a way of thinking that is impossibly idealistic. Of course, utopianism was, in some sense, never intended to be of this world; hence the weakness of many utopian communities, whether those of the Levelers or Diggers of mid-seventeenth-century England or the Branch Davidians of the late twentieth-century United States. Just as visions of possible futures arose out of political thought, numerous vibrant utopian experiments often emerged from religious splinter groups, whose promise of a better life both in the here and now and in the hereafter drew multiple generations of adherents. Examples of such groups are as different as the eighteenth-century Shakers (with their doctrine of celibacy) and the Church of Latter-Day Saints or Mormons (whose beliefs included plural marriage). Millenarian beliefs are common in utopian thinking, linking utopianism both to revolutionary and reactionary forms.

Between the hopeful utopianism of the nineteenth century and its opposite, the dreadful dystopianism of the mid-twentieth century, it is crucial to note a new form of utopian thinking and writing that arose during the first wave of feminist political struggle for suffrage at the turn of the nineteenth century. *Herland* (1915), a utopian fiction by the American reformer Charlotte Perkins Gilman (1860–1935), is a key text of this period of numerous writings by women that imagine a better place. However, it was the reissue of Gilman’s novel in 1979 that connected the first wave of feminist activism and imagination to the second wave of the later twentieth century. A noteworthy publication phenomenon of the 1970s and into the 1980s was the outpouring from mainstream and alternative presses of feminist utopian fictions. One of the best known is Marge Piercy’s *Woman on the Edge of Time* (1976).

The most important utopian thinker of the twentieth century is the German philosopher Ernst Bloch (1885–1977), whose magnum opus, *The Principle of Hope* (1954–1959), is a three-volume study of how hope her-
olds the new and the “not-yet” as it emerges in political and imaginary realms. Given the speculative nature of utopianism, it is not surprising that such thinking continues to evolve in the realm of political criticism and in genre writing, especially science fiction. An effort to keep up with utopianism and utopian criticism is maintained by the Society for Utopian Studies, which has been in existence since 1975. The society publishes a journal and a newsletter, sponsors an annual conference, and recognizes that utopianism emanates from disciplines as diverse as engineering, architecture, literature, and economics.

UZAWA, HIROFUMI

1928–

Hirofumi Uzawa was a native of Yonago, northwest Tottori Prefecture, on Honshu. His father was a schoolteacher. At the age of four, Uzawa and his brother moved with their parents to Tokyo, where they grew up. In 1948 he enrolled in the Department of Mathematics at the University of Tokyo, where he was chosen as a Special Research Fellow in the department. He received the BS degree in mathematics at the age of twenty-three in 1951, having majored in algebraic number theory. After receiving the BS Uzawa entered graduate school and taught mathematics at the University of Tokyo for five years.

To fully appreciate Uzawa’s formative years, one must keep in mind that when he was born the ruling power in Japan was the militaristic Meiji dynasty. This dynasty engineered the Japanese defeat of Russia in 1904, Japanese control of South Korea and Taiwan through League of Nations mandates after World War I (1914–1918), and Japan’s attack on Pearl Harbor in 1941. After Japan’s defeat, the U.S. military occupied the country from 1945 until 1952, and Japan was ruled by a military governor during that period. Japan’s September 1945 surrender resulted in its loss of control of South Korea and Taiwan, both of which then were occupied by U.S. troops. During its occupation of Japan, the United States engaged in a war in Korea, across the Sea of Japan from Uzawa’s birthplace. These events are implied in Uzawa’s autobiographical sketch, especially in his discussion of poverty, starvation, and underdevelopment in Japan.

While studying undergraduate mathematics and seeking to become a professional mathematician, Uzawa was led by the postwar poverty of Japan to study economics. He and several others began a systematic reading of Marxian economics. He contemplated joining the Japanese Communist Party but was advised by a friend who was already a member that he could not pass the entrance examination given to prospective members. He therefore decided to quit mathematics and study economics so that he could learn enough to pass the examination. But he did continue studying mathematics until he earned a degree.

After Uzawa graduated in 1951, he secured a job with the Institute of Statistical Mathematics at the Ministry of Education, and subsequently as a statistician with a life insurance company. During 1955 and 1956, he published four articles in the institute’s quarterly publication. The first two were purely statistical theory. The third was on Leontief input-output models. The last was “A Note on Preferences and Axioms of Choice.” Three years later, he published “Preference and Rational Choice in the Theory of Consumption.”

During the early 1950s, Uzawa remained actively affiliated with the University of Tokyo. He joined a small group of economists in the Faculty of Economics and read Keynes’s General Theory of Employment, Interest and Money and Kenneth J. Arrow’s Social Choice and Individual Values. He worked for six months in 1954 as an assistant to Everett E. Hagen (1906–1993) of MIT, who was in Japan with a mission of the World Bank. Hagen was in charge of macroeconomic analysis, and on this project, Uzawa first learned about Keynesian economic policy administration. In the summer of 1954, he also attended the annual joint University of Tokyo–Stanford University seminar conducted by Dutch economist Hendrik Houtakker (b. 1924) of Stanford on demand analysis. In this seminar, Uzawa was reintroduced to the work of Arrow of Stanford, and this time read everything he could by Arrow, including especially his work with Leonid Hurwicz on the feasibility and stability of the “allocative mechanism” of a socialist economy.

In economics, Uzawa studied under Hyoe Ouch (1888–1980), who led the fight to resuscitate the Ohara Institute for Social Research after World War II (1939–1945). This institute studied labor economics, Marxian economics, and social issues and published the
Journal of the Ohara Institute for Social Research, the Labor Yearbook, pamphlets, and a publications series. Keynesian economics in Japan began with Keynes's The Economic Consequences of the Peace, and A Treatise on Money.

In 1955, through Houthakker, Uzawa reviewed the unpublished manuscript of Kenneth J. Arrow and Leonid Hurwicz's article on local stability. Expanding on this article on his own, Uzawa wrote "Gradient Method for Concave Programming II: Global Stability in the Strictly Convex Case." His manuscript led to the receipt in 1955 of an invitation from Arrow to work with him at Stanford. Having become interested in pursuing a career in economics rather than mathematics, in 1956 he applied for and received a Fulbright Fellowship to finance the Arrow enterprise. He was a research assistant at Stanford from 1956 to 1964. Here, he was exposed to a rigorous mathematical treatment of neoclassical economics, Keynesian theory, and general equilibrium theory rather than Marxist economics. Uzawa published at least three papers in the Technical Reports series of the Stanford economics department between 1956 and 1958. Two of these papers contributed to the Houthakker research program in consumer economics, specifically his interest in preference functions.

In 1958 Uzawa, Arrow, and Hurwicz published Studies in Linear and Non-Linear Programming with the support of the U.S. Office of Naval Research. In this book, Uzawa presented a general mathematical theory. This book was concerned with deriving existence proofs for solutions to programs in linear topological spaces. These proofs involved the theory of convex polyhedral cones (CPC) in point-set topology, which are treated algebraically by means of analytical geometry. Using set theory and linear algebra, Uzawa presented the theory of topology on which the editors based the application to programming in the remainder of the book. Uzawa defined CPC conventionally as "the intersection of a finite number of half-spaces," that is, affine spaces bounded by hyperplanes. In the linear programming problem, the intersection of half-spaces creates a pyramid. The linear constraints of the problem constitute the edges of the polyhedron. The intersections of these edges constitute the vertices of the polyhedron. The solution algorithm evaluates each vertex in turn to find the one constituting the maximum or minimum. In the case of the pyramid, or three-dimensional polyhedron, four or five vertices must be evaluated, depending upon whether the base is a triangle or a square.

The gradient [slope] method is defined as the solution set to a system of differential or difference equations. The gradient is the ratio of the change in the slope of the plane triangle constituting one side of the pyramid. Further, the gradient method is applied to several particular problems, including economic development and growth. It is found that it is slower than the simplex method because it calculates all surface vectors to a linear programming problem, while the simplex method calculates only the optimum vectors, that is, only vertices. A simplex is the simplest form that can be constructed between points in a given space.

Uzawa remained away from Japan for thirteen years, serving on the faculties of the University of California at Berkeley (1960–1961), Stanford (1961–1964), Cambridge (1964–1965), and the University of Chicago (1965–1969). He was thoroughly immersed in the project to mathematize neoclassical economic theory. He left Stanford to attain intellectual independence. By 1960, he was married to his wife, Hiroko, and had children.

In 1968 Uzawa returned to the University of Tokyo as professor of economics until retiring to emeritus status in 1993. In 1973 and 1976, his interest shifted to the short-run fluctuations of a capitalist economy, or business cycles, and he published papers on Keynesian theory. In 1976, he served as president of the Econometric Society. Beginning around 1970, and continuing to the present, he has been senior advisor to the Research Institute of Capital Formation of the Development Bank of Japan. He also taught at Niigata University, Chuo University, United Nations University, and Doshisha University. From about 2003 to 2005, he was director of Doshisha University's Research Center of Social Overhead Capital.

Uzawa's general equilibrium analysis concluded that Walrasian tâtonnement mechanism is globally stable. This again was part of the project to study the nature of equilibrium mathematically but also of the project to renew general equilibrium analysis. Uzawa is most renowned, though, for the development of two-sector neoclassical endogenous growth models, and for a theory of economic growth. His method was taken from Marx's two-department model of simple reproduction in volume 1 of Das Kapital. The language and categories employed, however, were those of neoclassical economics. In these growth articles, he was disaggregating the one-sector models of Robert M. Solow (b. 1924) and T. W. Swan (1918–1989). The two sectors were a consumption sector and an investment sector, each using labor and capital to produce an output. The investment sector produced a capital good, and the consumption sector produced a consumption good. The production functions for each sector exhibited diminishing returns to scale. Technological change was not included in the Solow-Swan model, and so was exogenous. Uzawa included terms for technology in his model, thus endogenizing technological change. His articles stimulated an explosion of research into growth models in the 1960s, but this interest subsided thereafter. The practical motivation
driving his interest in growth was the underdeveloped state of the Japanese economy as he perceived it.

VACATIONS
The term vacation describes a moment of rest and recreation during sacred and secular holidays or a period of leisure time away from routine domestic responsibilities, school, or work, as allowed by present-day laws and labor regulations. The modern idea of vacationing is often linked to making a pleasure journey away from home, ranging from a simple daytrip nearby to a voyage around the world. In many countries, the notion is used interchangeably with the concept of holidays. As suggested in the volume edited by Graham Dann *The Tourist As a Metaphor of the Social World* (2002), understanding contemporary vacationing practices provides insight in the value systems of the modern world.

The notion of having a vacation is not universal. Even in industrialized societies, it did not exist until the 1850s, when the concept arose in response to time-regulated forms of labor. The clear bounding of work time was the product of victories by workers pressing for shorter workdays and scattered vacation days. The English entrepreneur Thomas Cook was the first to commercialize inexpensive package tours, designed for the short vacation time of the working class. From the 1930s, and accelerating in the postwar period, paid vacations in most European countries had been politically secured and came to be understood as a right of citizenship and part of a new social contract. In the United States modern vacations developed as a privilege accorded to workers as part of their employment package. During the 1970s and 1980s disposable incomes and annual days of vacation rose in developed countries, while the cost of travel remained more or less constant in real terms. This consequently led to a phenomenal rise in international tourism.

Legislation granting yearly vacation periods with pay and collective agreements providing for such holidays is increasingly common worldwide. Moreover, as standards of living improve, there is a marked tendency for the minimum annual vacation to be increased. The actual length of time is dependent on the length of service and provisions of the collective agreement. It can range from only a couple of days to more than six weeks. The rise in the number of international tourists from Asia—mainly the newly industrialized countries—illustrates the exportability of the vacation model to those countries where certain minimum requirements are met in terms of the availability and distribution of disposable income.

What people do during their vacation has changed over time, just as it has varied from country to country. Although vacationing has been democratized, vacations are still separate functions of differentials in income, social class, race, occupation, gender, and education. As Pierre Bourdieu described in great detail in his *Distinction: A Social Critique of the Judgment of Taste* (1984), there are substantial disparities in leisure consumption between people from different socioeconomic backgrounds. While working-class people often choose cheaply packaged mass tourism activities, the higher-class elites try to distinguish themselves by opting for expensive, individually tailored tours. Even if there is a clear global convergence in certain kinds of vacation consumerism, great local differences remain.

Vacationing is often thought of as a temporary reversal of everyday activities. It is a no-work, no-care, no-thrift
situation. However, in itself it is believed to be devoid of deeper meaning: It is a vacation; that is, vacant time. In a way, time is suspended (or put in parentheses) and many people believe to live a kind of absolute break of their habitual time. Conspicuous vacation is meant to be non-productive consumption of time, an indication of distance from environmental and productive needs, and thus a sign of wealth. The growing frequency of vacation travel in the developed world has ensured that vacation time is increasingly recognized as one of the experiences that people value in terms of quality of life.

The annual vacation trip in industrialized countries is a repetitive, predictable, timed break that allows people recreation and marks the progress of cyclical time. Therefore, vacations can also be characterized as a kind of ritual process that reflect a society’s deeply held values about health, freedom, nature, and self-improvement. In this view, vacations can be interpreted as the modern equivalent for secular societies of the annual and lifelong sequences of festivals and pilgrimages in more traditional, religious societies. Fundamental is the contrast between the ordinary/compulsory work state spent at home and the non-ordinary/voluntary (sacred) state away from home.

According to Orvar Löfgren in On Holiday: A History of Vacationing (1999), vacationing frequently involves temporal tensions and relations between past, present, and future. Traveling across space is frequently experienced as a movement across time to relive mythical periods of history, or former ways of life, or past stages from our life. Thus, it is not surprising that getting back to nature, to a more simple life, or to childhood—in other words freezing time—are common utopias of vacationers. Löfgren sees the world of vacationing as a place where tourists are able “to use the important cultural skills of daydreaming and mindtraveling … [in] an arena in which fantasy [is] an important social practice” (p. 7). The perceptions of vacationers are thus closely related to fictional worlds and, for the same reasons, to the world of dreams. The colloquial expression “dream vacation” did not appear without precedent.

Members of industrialized societies define their lives not only through their work but also increasingly through their consumption of vacations. The latter serve as a form of escape from the stresses, pressures, and demands of everyday life. People believe that the promise of personal freedom, one of the most expansive modern myths, can be fulfilled much more on vacation than in everyday life. Vacations become the ideal moment of self-realization in which people construct their own world according to their individual preferences. However, throughout the relatively short history of leisure travel, people have quickly learned how to be vacationers and to move; often according to social dictate, through different types of artificially created vacation worlds like theme parks and beach resorts. In many countries, a system of social sanctions is in place that variously codifies vacationing as “normal” or even expected behavior.

VAGABONDS
The English term vagabond derives from Latin and Anglo-Latin sources. The word literally meant to wander from bondage, but more idiomatically to escape from bondage. The etymology of bondage is also significant. Historically, forms of bondage in the West included slavery; serfdom, a system of partially unfree labor in rural societies; apprenticeship, which regulated entrance into and the practice of trades in towns; and systems of domestic service. To depart from any of these work situations without an employer’s permission was to risk charges of “vagabondage.” The Latin noun vagabundus appears in late medieval English manorial records, and according to the Oxford English Dictionary the English terms vagabond and vagrant date from the early 1400s. Since the fifteenth century, the same source shows, these words have been employed to describe anyone who was without fixed abode, unemployed, itinerant, or in an unlicensed trade. Of course, the terms vagabond and vagrant have also been used as terms of abuse, as have the synonyms beggar, bum, hobo, laofer, and tramp.

There are varying interpretations of vagabondage. One can be called the realist position, because it postulates that vagabondage reflected real economic and social causes, that the numbers of vagabonds were great and growing, that they were an underworld organized in gangs that engaged in professional crime, and that they posed genuine threats to the social and political order. A second interpretation emphasizes the power of the normative, especially notions about moralism and patriarchalism vis-à-vis dependents, including workers, which led to a growth of state intervention to enforce those norms. This position stressed the distinctions between the worthy and the
unworthy poor and contained an impetus to reform the latter group. This normative interpretation, in turn, readily accommodates theories of law and criminality that maintain that some offenses, including vagrancy, are products of governmental initiatives leading to “status criminality” and “social control.” The third view of vagabondage, which is the one favored here, is that the phenomenon was a combination of the real and the normative.

At the core of the concept of vagabondage were two key elements—voluntary unemployment and itinerancy—both of which, historically, were connected with labor and residence obligations of medieval serfdom. It cannot be a coincidence that European governments first began acting against vagabonds in the 1350s after the Black Death severely cut the population and made it possible for laborers to reject the obligations of serfdom. When population levels recovered after 1500, western European governments continued to enforce policies against vagabondage, which they found were useful weapons in the control of a workforce now largely liberated from serfdom. To police the labor force, vagrancy laws, Bridewells (houses of correction), and later workhouses were instituted from the sixteenth through the eighteenth century. These institutions lasted into the nineteenth century and were exported overseas to European colonies.

The policies against vagabonds also reflected a normative shift that desanctified the poor. Before this change the prevalent notion of the poor, inspired by the powerful example of St. Francis, idealized them as representing holiness, and Christians were encouraged to live like them. But in the thirteenth century some canon lawyers began to question whether the voluntary poor should be given relief. After 1350, moreover, Renaissance humanists argued for the positive benefits of wealth, which they argued allowed one to be a benefactor to one’s community. They also attacked the notion that poverty was a holy condition, pointing to the sins, disorders, and diseases that it fostered. They derided the hypocrisy of friars living in luxury and pilgrims wallowing in dissipation and called for the moral reform of the undeserving poor through institutionalization, including punishment and work-regimes.

Homelessness is obviously a less value-laden term than vagabond and is appropriate in a society in which the poor without permanent residences are no longer quite so demonized as they once were, but we should remember that homeless is a neologism that, like vagabond, requires analysis. In this respect, the term vagabond is more historically relevant during the approximately six hundred years of world history when it was applied to a great variety of people leading itinerant lives. The significance of the word lies in its rhetorical power and its suggestion of subversion of the social order. Ultimately, its power is its explicitness about the fact that governments criminalized and punished itinerants, who faced a two-fold challenge—homelessness to be sure, but also official demonizing and harassment.

What of the vagabonds themselves? They were not the simple equivalent of the homeless poor of the twenty-first century. Rather they resembled the “underclass” in society, in part because the authorities believed they had a distinctive culture that was opposed to respectable society. There were elements of a counterculture among vagabonds, including their use of slang, or cant, and some of them took part in organized crime. But for the most part their key characteristics arose from the structure of the economy and the labor system, particularly high unemployment and underemployment. Not all vagabonds were unemployed and begging, however; many practiced trades that were banned or subject to licensing, including unlicensed actors, itinerant healers, musicians, peddlers, practitioners of white magic, and sailors and soldiers. Overall, the key element in the lives of vagabonds was insecurity, which Olwen Hufton neatly summed up as living in an “economy of makeshifts.” Like gangs in modern cities, they were overwhelmingly young males, which frightened governments wary of violence and disorder. While foreign-born Romanies or “gypsies” were sometimes singled out in anti-vagrancy laws, the overwhelming majority of vagabonds were native-born.

Vaisyas

An upper class in the Hindu tradition, the Vaisyas are the lowest level of the “twice-born” (dvijas). They are commoners, but not a servant group. They undergo the sacred thread ceremony (Yajnopavita), as do the Brahmins and

SEE ALSO Hobos
Kshatriyas. But while male Vaisyas “take the thread,” it is made of a fiber different from that of the two castes above them (Brahmins and Kshatriyas). As part of the cosmic order of dharma, they have been assigned the role of merchants and craftspeople.

Vaisyas are described in the Laws of Manu (a Hindu sacred book) as being given at creation the duties to tend cattle, bestow gifts, offer sacrifices, trade, lend money, cultivate land, and study the Vedas. It is sacreligious for a Vaisya to refuse to keep cattle. In trading it is the duty of Vaisyas to know the value of pearls, coral, metals, and other commodities.

The Laws of Manu charge Vaisyas with acquiring skills in good management of those they employ. They need to know languages, proper wages, and how to operate a business so that goods are properly stored and traded. These tasks are also to be done with exertion so that the wealth of the Vaisyas can increase, but in a righteous manner. It is also a Vaisya duty to give food to all creatures. Additionally, the Laws of Manu includes rules for accepting the testimony of Vaisyas and for their purification or their punishment in cases of adultery, murder, or other crimes.

Within the Vaisya caste there are subcastes of bakers, sheepherders, cowherders, agriculturalists, musicians, metal workers, and as well as traders and businessmen. All are people with a skill, trade, or profession.

In the myth of Purusha the Vaisyas were made from the god’s stomach. The Vaisyas resemble the Platonic people of bronze who are the people of the “belly.” They are the farmers, herders, merchants, and businesspeople who produce and distribute food and other needed goods to society.

The Bhagavad Gita assigned the Vaisyas the duties of farming, protecting the cows of India, and conducting business. Their way of life demands labor, study, sacrifice, and the giving of alms. On special days, giving to the Brahmin is a common practice. According to the Bhagavad Gita, Vaisyas are such an essential element in society that it cannot survive without them.

Vaisyas were expected to be specialists in the trading of jewelry, precious metals, spices, or other goods. They were often vegetarians and very devout practitioners of their religion. Many are devotees of Laksmi, wife of Vishnu and the goddess of wealth.

An important Vaisya subcaste are the Mahuri Vaisyas. They are believed to have emigrated from around the city of Mathura as well as from Vrindavan and Gokul to the Bengal area during the time of the Mughal Empire (1526–1827). They also comprise a religious community worshipping Mata Mathurashani Devi, an incarnation of the goddess Shakti.

Some of the Mahuri claim that they originated from the creative work of Krishna who made them as gopas and gopis (cowherders), but then gave them the task of earning their living from trading. Their surnames are derived from the names of the forest villages where they were originally placed. These surnames include Athaghara, Badgawari, Barahapuriya, Bhadani, Charanpahari, Ekghara, Gowardhan, Kandhaway, Kapasimey, Krishan-kunda, Kutariyaar, Lohani, Panwachaudaha, Seth, Tarway, and Vaishakhiyar. Each clan has legendary stories that tell of their origins in remote areas where in some cases there are still temples dedicated to cows. Besides folklore, however, there is little that can be substantiated about them that is more than four hundred years old.

Around 1750, many Vaisyas migrated to the Chota Nagpur Plateau where they still maintain villages. Others are now located in western Bengal and Orissa. Many are also traders in New Delhi, Chennai, and Mumbai (Bombay). Small numbers are located around the world.

Modern Vaisyas practice business and agriculture but with ethical practices in keeping with the modern global society. They practice environmentally sound agriculture that entails protecting the environment rather than exploiting it. This is an application of their role as cow protectors.

VAJPAYEE, ATAL BIHARI 1924–

Former Indian prime minister Atal Bihari Vajpayee is renowned for his political, literary, and professional achievements both in India and internationally. His major noteworthy accomplishments, prior to more than four decades of political participation and dynamic leadership, include his education at Victoria College (now Laxmibai)
in Gwalior and DAV College in Uttar Pradesh, editing of several Indian periodicals, and composition of a variety of literary works. Vajpayee holds a Master of Arts degree in political science. He served as editor of the monthly Rashtra-Dharma, the weekly Panchajanya, and the daily Swadesh and Veer Arjun periodicals. His own major publications, including Lok Sabha Mein Atalji, Mrityu Ya Hatya, Amar Balidan, Kaidi Kavirai Ki Kundalian, New Dimensions of India's Foreign Policy, Jana Sangh Aur Musalman, Three Decades in Parliament, Amar Aag Hai, Meri Elyawan Kavitayen, and Four Decades in Parliament, range from books to collections of poems and compilations of speeches.

Vajpayee was born on December 25, 1924, in Gwalior, in what is now Madhya Pradesh, India. In the early 1940s he first became interested in the Indian independence movement. His first party affiliation was as a member of the Quit India Movement, which was lobbying for the end of British control of India. A devout Hindu, in 1951 he was a founding member of the Bharatiya Jana Sangh (BJS) Parliamentary Party, and because of his dynamic pro-Hindu, right-wing political leadership, he led the party for two decades, from 1957 to 1977. He was briefly imprisoned during the Indian Emergency of 1975 to 1977 because of opposing Prime Minister Indira Gandhi's state of emergency. After the BJS was merged into the Janata Party, Vajpayee was elected minister of external affairs. In 1980 he was elected president of the Bharatiya Janata Party (BJP), another Hindu fundamentalist party, a post he held until 1986. He then rose to become the leader of the National Democratic Alliance (NDA), which from 1998 through 2004 was the ruling coalition of India, and from this position he was named prime minister. In addition to championing the cause of Hindu nationalism, Vajpayee has also actively worked on behalf of women and children's welfare, and the elevation of lower caste and tribal people. His advocacy in these areas might seem paradoxical and contradictory if only seen within his attachment to the BJP, but one should consider that, more than anything else, Vajpayee was a popular intellectual leader seeking to expand his political power. So his advocacy for social justice can be viewed in part within his larger effort to advance both his political power and the BJP's influence. His advocacy in these areas might seem paradoxical and contradictory if only seen within his attachment to BJP, but one should consider that, more than anything else, Vajpayee was a popular intellectual leader seeking to expand his political power. Undermining 50 percent of the Indian population would have jeopardized both his power and BJP's rising influence. This paradox can also be seen in the case of Indira Gandhi, who was a well known left winger female leader, but with much less practical sympathy for women's welfare and social justice.

In addition to serving twice as prime minister of India, Vajpayee is the only person to have been elected nine times to the Lok Sabha, or Indian House of the People. He was first elected to the second Lok Sabha in 1957, and most recently to the thirteenth Lok Sabha in 1999. Twice he was elected to the Rajya Sabha, or House of the States. He was the only leader besides Pandit Jawaharlal Nehru to be elected prime minister by three consecutive terms in office (in 1996, 1998, and 1999). During his tenure as prime minister, he successfully managed the political fragmentation that has typically plagued the Indian government. Under his leadership, in spite of an economic recession, India logged impressive growth in various economic indicators, including foreign exchange reserves, agricultural production, and gross domestic product.

Vajpayee has participated in numerous parliamentary committees, social and cultural associations, and Indian delegations to the European Parliament, the UN General Assembly, Human Rights Commissions, and other international conferences.

In December 2005, Atal Bihari Vajpayee expressed a decision to entrust the future of Indian politics to other capable leaders, formally announcing his retirement from electoral politics.

VALIDATION
Before social scientists can study the feelings, thoughts, behaviors, and performance of individuals, and before practitioners (such as therapists, case managers, or school staff) can respond to clients' problems in those areas, they
must be able to measure the phenomena in question. Measurement tools include measures, instruments, scales, indices, questionnaires, and surveys. Complex social constructs such as “depression,” “worker satisfaction,” or “reading achievement” cannot be assessed with one question. A depression scale, for example, requires multiple questions (or items) to fully capture depression’s affective, cognitive, and physical dimensions. An individual’s responses to multiple items on a scale are typically combined (e.g., averaged or summed) to give one composite score. Measurement validation is the process of demonstrating the quality of a measure, the scores obtained with the measure, or the interpretation of those scores. Validation is necessary because scores from measures may be inaccurate. Respondents may misunderstand items, deliberately provide inaccurate responses, or simply lack the knowledge or ability to provide accurate responses. Specific items or the scale as a whole may not accurately reflect the target construct.

A common textbook definition of validity focuses on how accurately and completely a measure captures its target construct. From this perspective, measures can be sufficiently validated based on evidence of content validity, criterion validity, and/or construct validity (see Table 1). Validity is considered a characteristic of measures and is a demonstrable goal. For example, a scale developer might claim that a new worker-satisfaction scale is valid after presenting results of analyses of content and criterion validity.

This approach to validation as it is commonly applied has a number of shortcomings. First, it focuses narrowly on item content and score performance. Second, as elaborated by Kenneth A. Bollen (1989), it ignores potential problems with traditional correlational analyses, including the possibly erroneous assumption that scores from the existing measures used for comparison are valid. Third, it relies on indirect methods of assessing whether respondents interpreted items and response options as intended.

A broader view of validation defines it as an ongoing process of building a case that (1) scores obtained with a measure accurately reflect the target construct and (2) scores obtained with the measure can be interpreted and used as intended. This view implies that validation is an unending, multifaceted process and that it applies to the interpretations of scores obtained with a measure, not the measure itself. It also suggests that evaluating how scores are interpreted and used is essential to the validation process. This last point implies a legitimate role for values and ethics in the evaluation of measures. Proponents of elements of this broader view include measurement scholars from numerous social science disciplines—for example, Robert Adcock and David Collier (2001), Kenneth A. Bollen (1989), Lee J. Cronbach (1988), Samuel Messick (1988), and Howard Wainer and Henry I. Braun (1988), as well as a trio of social science professional organizations: the American Educational Research Association, the American Psychological Association, and the National Council on Measurement in Education (American Educational Research Association et al. 1999). From this broad view of validation and validity, the approach to validation presented in Table 1 is inadequate.

Table 2 presents components of a broad view of measurement validation. The components of Table 1 are present (in rows 1 and 2), but other evidence is considered necessary to validate the interpretation and use of scores. Additional statistical procedures that are often used in scale development but less often presented as evidence of validity are also included (in rows 1 and 3). Corresponding categories of validation evidence described in the Standards for Educational and Psychological Testing (1999) are listed

Other assumptions commonly associated with this view: Measures are validated; validity can be “proven”; there are different types of validity.

Table 1
under the terms in the first column. It is unlikely that any validation process will include all elements in the table, but the more sources and methods used, the stronger the case for validation will be.

RESPONDENT-RELATED VALIDATION

A direct method of assessing whether a scale measures what it is intended to measure is to interview pilot test subjects about their interpretation of items. Gordon B. Willis (2005) and Stanley Presser et al. (2004) provide detail on cognitive interviewing techniques. Data collected can be analyzed (usually qualitatively) to identify problem words or concepts and evidence that items or response options were misunderstood. Establishing that respondents interpret original or revised items as intended can contribute significantly to the validation case for a measure’s score interpretations.

Demonstrating that respondents understand, interpret, and respond to items as intended is evidence of what Kevin Corcoran (1995, p. 1946) has referred to as the “suitability and acceptability” of a measure for its intended population. More specifically, it may constitute evidence of developmental validity (the content and format of a scale are appropriate for the cognitive, attentional, and other abilities of individuals). Natasha K. Bowen, Gary L. Bowen, and Michael E. Woolley (2004) and Michael E. Woolley, Natasha K. Bowen, and Gary L. Bowen (2004) discuss the concept of developmental validity and a sequence of scale-development steps that promote it. The process may also generate evidence of cultural validity (the content and format of a scale are appropriate in relation to the experiences of individuals that may vary based on language, nationality, race/ethnicity, economic status, education level, religion and other characteristics). Although these examples are presented as types of validity, they are easily reframed as evidence of validation that supports confidence in the interpretation of scores obtained from respondents with different characteristics.

Certain statistical analyses of scores obtained with a measure, such as multiple group factor analysis, can also support respondent-related validation. The analyses may provide statistical evidence that scores obtained from members of different groups (e.g., males, females; members of different cultural groups) can be interpreted the same way.

PRACTICE-RELATED VALIDATION

Some measurement scholars, such as Cronbach (1988) and Messick (1988), stress that the uses and consequences of scores must be considered in the validation process. Messick states: “The key validity issues are the inter-
pretability, relevance, and utility of scores, the import or value implications of scores as a basis for action, and the functional worth of scores in terms of social consequences of their use” (p. 33). Practice-related validation requires researchers to examine the context in which a measure is to be used—the setting, the users, and the intended uses of the measure. As demonstrated by Natasha K. Bowen and Joelle D. Powers (2005), practice-related validation of a school-based assessment might include evidence that the construct measured is related to achievement, evidence that school staff who will use the scores currently lack (and want) the information provided by the measure, and evidence that resources exist at the school for addressing the threats to achievement revealed in the obtained scores.

As pointed out by Cronbach (1988), evaluation of the context and consequences of score interpretations necessarily involves a consideration of values. The consequences of decisions based on scores may determine “who gets what in society” (p. 5). Standardized school test scores, college entrance exams scores, and mental health screening scores, for example, may be used to determine, respectively, who gets what instructional resources, who goes to college, and who receives mental health services. Given how the use of scores from social science measures affects the distribution of resources and the opportunities of individuals to succeed, a broad, thorough, ongoing approach to the validation process is an ethical necessity for social scientists.

VALIDITY, STATISTICAL

A study is valid when it actually measures what it claims to measure and when there are no logical errors in the drawing of conclusions from the data. There are many labels for different types of validity, but all concern threats that undermine the meaningfulness of research. Some early writers simply equated validity with establishing that a construct’s scale correlated with a dependent variable in the intended manner, and, indeed, a scale might be considered valid as a measure of anything with which it correlated (Guilford 1946). Types of validity were codified in 1954 by the American Psychological Association (APA), which identified four categories: content validity, construct validity, concurrent validity, and predictive validity. Each type corresponded to a different research purpose: Content validity had to do with subject-matter content testing; construct validity with measuring abstract concepts like IQ; concurrent validity with devising new scales or tests to replace existing ones; and predictive validity with devising indicators of future performance. A 1966 update to the APA typology combined the last two types under the label criterion-related validity. Later, Lorrie Shepard (1993) was among those who argued that both criterion and content validity were subtypes of construct validity, leaving only one type of validity.

The unified view of validity supported the notion that only rarely could a researcher establish validity with

Natasha K. Bowen
reference to a single earlier type. Moreover, Lee Cronbach's (1971, p. 447) earlier argument that validity could not be established for a test or a scale, but only for interpretations that researchers might make from a test or a scale, also became widely accepted in the current era. Some researchers, such as Samuel Messick (1989), accept construct validity as the only type of validity, but argue for multiple standards for assessing it, including relevant content based on sound theory or rationale, internally consistent items, external correlation with related measures, generalizability across populations and time, and explicitness in social consequences (e.g., racial bias). In a nutshell, since about the mid-twentieth century, the concept of validation has evolved from the establishing of correlation with a dependent variable to the idea that researchers must validate each interpretation of each scale, test, or instrument, and do so in multiple ways that taken together form the whole of what validity testing is about.

The outline below largely accepts the unified view of validity, centering on construct validity, but adds to it separate coverage in three areas: (1) content validity, focusing on the labeling of constructs; (2) internal validity, focusing on research design bias; and (3) statistical validity, focusing on meeting the assumptions of empirical procedures. While all three might be (and by some are) considered subtypes of construct validity, they do not fall neatly in its two major subdomains—convergent and discriminant validity—and so have been treated here separately.

**CONSTRUCT VALIDITY**

Under construct validity (or factorial validity), a good construct has a theoretical basis that is translated through clear operational definitions involving measurable indicators. A poor construct may be characterized by lack of theoretical agreement on content, or by flawed operationalization such that its indicators may be construed as measuring one thing by one researcher and another thing by a second researcher. To the extent that a proposed construct is at odds with the existing literature on related hypothesized relationships using other measures, its construct validity is suspect. The more a construct is used, in more settings with more outcomes consistent with theory, the more its construct validity.

**Convergent Validity** Researchers should establish both of the two main types of construct validity: convergent and discriminant. Convergent validity is assessed by the correlation among items that make up the scale or the instrument measuring a construct (internal-consistency validity); by the correlation of the given scale with measures of the same construct using scales and instruments proposed by other researchers and, preferably, already accepted in the field (criterion validity); and by the correlation of relationships involving the given scale across samples (e.g., racial tolerance using subject data versus spousal data) or across methods (e.g., survey data versus archival data).

Internal-consistency validity seeks to establish at least moderate correlation among the indicators for a concept. Cronbach's alpha is commonly used, with .60 considered acceptable for exploratory purposes, .70 adequate for confirmatory purposes, and .80 good for confirmatory purposes. Other tests used to demonstrate convergent validity include demonstrating a simple factor structure, employing the one-parameter logistic models developed by Georg Rasch (1960), or using the average variance extracted (AVE) method developed by Claus Fornell and David Larcker (1981).

Criterion validity (or concurrent validity) has to do with the correlation between measurement items and accepted measures. Ideally, the criteria are direct, objective measures of what is being assessed (e.g., how well does survey-reported voting correlate with actual voting in voting records?), but correlation with well-accepted related scales is an alternative criterion.

**External validity** has to do with possible bias in the process of generalizing conclusions from a sample to a population, to other subject populations, to other settings, or to other time periods. The questions raised include: "Are findings using the construct scale consistent across samples?" and "To what population does the researcher wish to generalize conclusions, and is there something unique about the study sample's subjects—the place where they lived and worked, the setting in which they were involved, the times of the study—that would prevent valid generalization?" When a sample is nonrandom in unknown ways, the likelihood of external validity is low, as in the case of convenience samples. External validity may be increased by cross-validation, where the researcher develops the instrument on a calibration sample and then tests it on an independent validation sample.

**Discriminant Validity** Discriminant validity, the second major type of construct validity, refers to the principle that the indicators for different constructs should not be so highly correlated as to lead one to conclude that they measure the same thing. This could happen if there is definitional overlap between constructs.

Discriminant validity analysis may include correlational methods, factor methods (Straub 1989), the AVE method, and structural equation modeling (SEM) approaches. In confirmatory factor analysis within SEM, if goodness-of-fit measures for the measurement model are adequate, the researcher concludes that the constructs in the model differ. A more rigorous and widely accepted SEM-based alternative is to run the model unconstrained and also constraining the correlation between constructs.
to 1.0. If the two models do not differ significantly on a chi-square difference test, the researcher will fail to conclude that the constructs differ (Bagozzi et al. 1991).

CONTENT VALIDITY
Content validity (or face validity) exists when items measure the full domain indicated by their label and description. A *naming fallacy* exists when indicators display construct validity, yet the label attached to the concept is inappropriate (e.g., satisfaction with outcomes is measured but is labeled as effectiveness of outcomes). A *domain fallacy* exists when indicators are restricted in value (e.g., “monetary incentives” may be the label of an indicator in a small group simulation, but the indicator would be more accurately labeled “small monetary incentives” due to restricted range; the label “large monetary incentives” may have a very different effect).

INTERNAL VALIDITY
Internal validity concerns defending against sources of bias arising in research design. When there is lack of internal validity, variables other than the independent(s) being studied may be responsible for part or all of the observed effect on the dependent variable(s). If there is no causal phenomenon under study, internal validity is not at issue.

Common issues related to internal validity are:

- **Hawthorne effect** (experimenter expectation): The expectations or actions of the investigator may contaminate the outcomes.
- **Mortality bias**: Attrition of subjects later in the research process may render the final sample no longer representative.
- **Selection bias**: The subjects may not reflect a random sample, and when multiple groups are studied, there can be differential selection of the groups associated with differential biases with regard to history, maturation, testing, mortality, regression, and instrumentation (i.e., selection may combine differentially with other threats to validity).
- **Evaluation apprehension**: Study sponsorship, phrasing of the questions, and other steps taken by the researcher may not suffice to mitigate the natural apprehension of subjects, encouraging a bias toward responses the researcher is thought to want to hear.

Special problems involving control groups include:

- **Control awareness**: If the control group is aware it is not receiving the experimental treatment, it may exhibit compensatory rivalry, resentful demoralization, or other traits that may contaminate study results.

**Compensatory equalization of treatments**: Researchers may compensate for the control group’s lack of benefit from treatment by providing some other benefit, such as alternative experiences, thereby introducing unmeasured variables.

**Unintended treatments**: Researcher attention, the status of the testing locale, and other testing experiences may constitute unmeasured variables.

Likewise, special problems exist for before-after and time series studies:

- **Instrumentation change**: Measurement of variables may shift in before-after studies, as when the observers, through experience, become more adept at measurement.
- **History**: Intervening events that are not part of the study may occur between measurement intervals, affecting results.
- **Maturation**: Invalid inferences may be made when the maturation of subjects between intervals has an effect.
- **Regression toward the mean**: If subjects are chosen because they are above or below the mean, there is a statistical tendency that they will be closer to the mean on remeasurement, regardless of the intervention.
- **Test experience**: The before-study impacts the after-study in its own right, or multiple measurement of a concept leads to familiarity with the items and hence a history or fatigue effect.

STATISTICAL VALIDITY
Statistical validity concerns basing conclusions on a proper use of statistics, and in particular whether the assumptions of statistical procedures are met (e.g., normality, homoscedasticity, independence, and other traits may be required). Statistical invalidity also occurs when the researcher has not properly specified the model, has not taken interaction and nonlinear effects into account, or has misinterpreted the causal direction of relationships.

When significance tests are employed, they may be invalid if data are not randomly sampled, if an inappropriate alpha level has been selected (e.g., .05 is common in social science but is too liberal for medical research), if the test has an inadequate power level, or if a post hoc “shotgun” approach is used in which large numbers of relationships are examined without taking into account that multiple a posteriori tests require a higher operational alpha significance level to achieve the same nominal level.

VALIDITY IN PSYCHOLOGY

SEE Validity, Statistical.

VALUE

In the work of Karl Marx the term value is defined as the labor embodied in the production of commodities, where commodities are goods produced for sale on the market. The concept of value applies only to commodity-producing economies, and the value of any particular commodity is the amount of labor required for its production according to the prevailing technological standards, assuming that the total output level is appropriate to market demand for the good. The embodied labor that defines the values of commodities includes that required to produce the intermediate goods needed in the production of these commodities as well as the direct labor inputs involved. Thus machines are regarded as passing on the labor embodied in them during their own production to what they themselves help produce. Different forms of direct labor are reduced to a common standard by applying a similar principle in calculating the amount of labor required to produce the various skills of different types of labor. More highly skilled labor therefore contributes more value to the production of commodities than does less skilled labor.

It follows that the value of any commodity can be divided into two parts: the dead labor inherent in the intermediate goods employed in production, and the living labor arising from the use of workers of various levels of skill. Marx also subdivides the value contributed by direct labor into a magnitude equal to the value of the commodities contained in the wages received by workers, and a residual magnitude called surplus value which, he believed, constituted the basis of nonwage incomes in capitalism: profits, interest, and rents.

Marx’s concept of value is distinct from any notion of use-value, or utility. He knew that commodities are useful in production or consumption, but he believed that their usefulness has nothing to do with their value, which is determined solely by their conditions of production. Value as Marx defined it is also distinct from exchange value, or price. However, Marx used his value categories to provide a theory of prices in competitive capitalism. He made no claim that values directly determine prices, in the sense of being equal to, or even proportionate to, the prices of the commodities in question. The determination is more complex, and the prices Marx was concerned to explain are only long-period equilibrium prices. These are the prices that prevail in a situation where supplies are fully adjusted to demands in all lines of production, and the rate of payment of all inputs of the same type is equal.

VALIUM

SEE Psychotropic Drugs.
in all lines of production. He conceived of long-period equilibria as centers of gravitation to which market prices tend, and in doing so Marx placed himself in a long tradition of economic thought that took labor costs to be the key to a proper understanding of such prices, including Adam Smith in the late eighteenth century and David Ricardo in the early nineteenth. This history is examined in great detail and with considerable lucidity by Ronald Meek in his Studies in the Labor Theory of Value (1976). However, Marx also argued that the concept of value and derivative concepts, like surplus value, provided the basis for the correct understanding of much more than equilibrium prices.

In the three volumes of Capital, written in the 1860s, he also made the following three claims. First, surplus value represents exploited (unpaid) labor and all forms of property income in capitalism derived from this. Second, capitalism is therefore an economic system based upon the extraction of unpaid labor from producers by nonproducing classes and, thus, is analogous to systems of production based on slavery and serfdom. Third, as a result, the conflict between workers and property-owners has a structural foundation comparable to the class conflicts of earlier modes of production that had helped to destroy them. Marx argued for these three propositions at considerable length and with great sophistication. But the basic message is straightforward: While capitalism appears to be very different from other types of economy in being grounded in free contract rather than coerced labor, the reality is less dissimilar. Capitalism, too, has an exploitative character and generates conflicts that will contribute to its transcendence.

Like Smith and Ricardo before him, Marx was well aware that values could not account for prices in any simple way. Outside of special circumstances, all three theorists recognized that equilibrium prices would not be equal to values. Smith believed that when property incomes (profits, interest, and rents) existed, values could not provide any explanation of prices whatsoever; they were relevant for understanding prices only in so-called “early and rude” societies where property had not been privatized. However, Smith continued to believe (in some unspecified sense) that labor was the only “true” cost of production, and he sometimes measured prices by the labor they could command in exchange. He was followed here by Thomas Malthus. David Ricardo proved more insightful, refuting Smith’s claim that the very existence of property incomes undermined the capacity of values to explain equilibrium prices. But outside of special circumstances he, too, recognized that values would not be equal to, or proportional to, prices. Some commodity prices would exceed their values and some would fall short of their values, since in equilibrium an equal rate of profit on capital is paid in all lines of activity and the equilibrium price has to be sufficient to allow payment of this rate of profit whatever the capital-intensity of production. It followed from this that the surplus value generated in any line of production would not typically correspond to the property incomes derived from that line of production. Marx sought to resolve this problem by showing that, for capitalism as a whole, prices are transformed values and property incomes are transformed surplus values. Values and surplus values are reallocated between lines of production according to the requirements of long-period equilibrium. So, he maintained, for the capitalist system as a whole, values and surplus values really do determine prices and property incomes. This was the basis for his social and historical claims concerning the exploitative and conflictual nature of capitalism.

CRITICISMS

Marx’s arguments for the illuminating power of value theory have not proved to be robust, although the central analytical difficulties came to light only in the 1960s, and most earlier criticisms have turned out to be rather weak in comparison. Marx himself was unable to specify rigorously the exact relationship between value magnitudes and price and income magnitudes. His critics, beginning with Ladislaus von Bortkiewicz in 1907, were much more successful. On the basis of reasonable assumptions about technology (as judged by the standards then prevailing in economics), Bortkiewicz and others proved that Marx’s claims with regard to the transformed nature of prices and incomes can be justified. In their The Political Economy of Marx (1988) authors Michael C. Howard and John E. King have outlined the technicalities of the proofs; and they have explained the proofs’ historical development in their two-volume A History of Marxian Economics (1989 and 1992). Despite this, Marx’s claims are true only under restrictive assumptions. Most particularly, when technologies involve joint production, in which more than one type of output results from a production process, or when there are alternative techniques for producing any particular commodity, there may be no sensible way in which commodity values can be computed. Furthermore Ian Steedman, in his work Marx After Sraffa (1977), showed that even when commodity values can be determined, they may not be able to provide a coherent theory of exploitation in terms of surplus value, so that property incomes and class conflicts cannot be explained in the way Marx believed.

It might reasonably be expected that the flaws in a theory as grand as Marx’s value theory would only succumb to something equally grand, not to the mundane fact commodities can be produced jointly in a single process, or that there are alternative processes in which they can be produced. But Marx was not alone in this.
Many of the propositions in Smith's economics, and even more in that of Ricardo, are also undermined. Similarly, Austrian capital theory and aggregate versions of neoclassical economics do not survive unscathed, as is proved with great economy and elegance in Production of Commodity by Means of Commodities (1960) by Piero Sraffa. Scholars of all schools made the huge mistake of believing that the complexities inherent in joint production and alternative production processes would not undermine results deduced from analyzing simpler and less realistic technologies. An element of irony is also present. Von Bortkiewicz and others who attempted to show rigorously that prices were transformed values, and property incomes were transformed surplus values, were not supporters of the political project of Marxism, while those who elucidated the destructive consequences of joint production technologies and alternative techniques of production were much more sympathetic to socialist politics.

However, the weakness of Marx's value theory does not fatally undermine Marxism as an intellectual force. Some scholars have continued to defend modified impre- sive versions of Marx's account of equilibrium prices, exploitation, and conflict, but without utilizing the concepts of value or surplus value. Three versions are Heinz Kurz and Neri Salvadori's Theory of Production: A Long Period Analysis (1995); John Roemer's A General Theory of Exploitation and Class (1982); and Gerry Cohen's Karl Marx's Theory of History: A Defense (2000). The ideas presented in these books and other works in the same vein are discussed in the second volume of A History of Marxian Economics by Howard and King. Also Marx's account of capitalist development and crises can be formulated in terms that are entirely independent of his theory of value and is thus unaffected by the difficulties that this theory has encountered.

VALUE ELICITATION

SEE Value, Subjective.

VALUE, OBJECTIVE

Within the social sciences, the concept of value was initially associated with the discourses of classical political economy, modern economics, and the Marxist critique of capitalism, and was later extended to refer to ideas of what is morally or ethically “right” or “important” in social life and in individual behavior. Thus, value can refer to both “economic values” and “cultural values”—that is, to the valuation of goods and services being bought and sold in the market, as well as to the ideals, principles, and goals that people define for themselves as they pursue the “good life” and the “good society.” An objective value is a value that has a universal, transhistorical, or transcultural foundation. As such, it is a concept in opposition to the notion that values are always subjective and relative, and reflect the predilections, choices, and preferences of individual social or economic actors.

OBJECTIVE VALUE IN ECONOMIC THEORY

The idea that a good or service produced for sale in the market possesses a value that is distinct from its price is fundamental to all theories of economic value. All such theories proceed from the assumption that a commodity's value is in some sense the “center of gravity” around which its price generally oscillates. For the physiocrats, this center of gravity was the productivity of agricultural labor; for the Smith-Ricardo classical school, the labor expended in the commodity's production; for Marx, the abstract labor required for the commodity's reproduction as measured by socially necessary labor time; for John Stuart Mill, the commodity's costs of production; and for the marginalists, its marginal utility to a prospective buyer.

Prior to the marginalist revolution in modern economic thought, the concept of value was treated invariably as an “objective” one. The value of a commodity was conceived as the sum of the value of the objective inputs to its production (living labor, raw materials, energy, and fixed capital depreciation). Sometimes these inputs were
subsumed under one or another version of the “labor theory of value” and sometimes under a “cost of production” theory. But it was generally taken for granted that an intimate connection existed between the “objective value” represented by, or embodied in, a commodity and its market price.

The most important theorist of objective economic value was Karl Marx, who recognized the revolutionary implications of the idea that value exists as a definite (objective) quantitative magnitude that sets parametric limits on prices, profits, and wages. Transforming the classical labor theory of value, Marx argued that living labor was the sole source of new value and that the contradictions inherent in the “law of value” were at the heart of the “laws of motion” of the capitalist mode of production. As living labor is displaced from commodity production as a result of technological innovation and capitalist competition, the capitalist system deprives itself of the “social substance” (labor value) that is its lifeblood, and the rate of profit falls, setting the stage for capitalist crisis and ultimately social revolution. Hence, Marx’s understanding of the “objectivity” of economic value as rooted in historically specific relations of production is integral to his account of the decline of capitalism and its supersession by a new socialist society that will be liberated from the tyranny of the law of value.

If Marx’s theory represented the logical outcome of the classical school’s commitment to a theory of objective economic value, it is unsurprising that economists committed to the perpetuation, reform, or fine-tuning of modern capitalism were eager to abandon it. The marginalist school of Carl Menger, William Stanley Jevons, and Léon Walras transformed the concept of economic value into an essentially subjective one, insisting that a good’s value is determined solely by its marginal utility and that value is merely a psychological relation between a commodity and a potential purchaser.

OBJECTIVE VALUE AS A CULTURAL PHENOMENON
Friedrich Nietzsche was the first modern thinker to project the concept of value outside the sphere of economics (and mathematics) to the sphere of culture, arguing that individuals were motivated less by the “virtues” celebrated by classical philosophy than by “values” that reflected their own interests, proclivities, and tastes. His subjective concept of value was to deeply influence the social theory of Max Weber, for whom the subjective value orientation of individual social actors was a fundamental starting point of sociological analysis.

The concept of objective cultural or moral values developed in reaction to the relativism and subjectivism of Nietzschean philosophy and Weberian social theory. Both liberal-democratic and Marxist-socialist versions of the concept have been elaborated, but they are united by the idea that some core human values transcend location, time, and culture and that these values therefore possess an “objective” character.

VALUE, SUBJECTIVE
The concept of subjective value is that each individual has their own preferences for objects or actions. This concept is applied by economists to understand behavior and operates “behind the scenes” of observed behavior. That is, preferences are part of a theoretical structure to explain behavior that is latent and are assumed to model the observed behavior. Thus it is common for economists to make statements such as “the individual is assumed to behave as if he or she has subjective preferences and values for this outcome” and then test the implications of that assumption. It is not the case that one can directly observe subjective preferences or subjective value. Instead, auxiliary assumptions are needed to infer subjective preferences or value.

The justification for subjective value is primarily a priori. It is easy to just imagine that people have different preferences for the same goods or actions; for example, one person likes red wine with most food, and another likes beer with most food.

What leads to the assumption of subjective value is that people seem to make different consumption decisions, even when the circumstances are otherwise the same. Imagine people deciding between two types of cars but having the same incomes and facing the same car prices. If we observe people choosing different cars or one
person not buying a car at all, how do we explain this outcome? We could claim that there are some unobserved differences in people’s constraints—for example, one person might live close to good public transport. Should one always ascribe differences in behavior to differences in subjective value or, instead, assume constraints that are specific to the decision maker but not observable to others? The answer to this question is one of the practical considerations that comes up repeatedly in theoretical and empirical work in economics (e.g., Stigler and Becker 1977; Becker 1993).

The concept of subjective value has direct implications for the manner in which we determine what valuations people have. This is the area of subjective value elicitation. It also has implications for how we design policy. The concept of consumer sovereignty flows naturally from thinking about subjective value: We value what is a good wine by seeing what people are willing to pay for it. But there are two concerns with the notion of consumer sovereignty that flows from thinking of values as subjects. First, what if those values are “constructed” by others, such as marketing, or the addiction that comes from some drugs? Second, it is possible, and indeed likely in some settings, that subjective value is not based on a complete processing of all of the relevant information about the consequences of actions. Hence society may want to adopt valuations that differ from those that individuals would adopt.

WHY ELICIT SUBJECTIVE VALUES?

Economists are interested in eliciting subjective values at the level of the individual because market values do not provide the information needed to measure consumer surplus, value new products, or value goods that have no market. Why do we need to elicit values? The prices observed on a market reflect, on a good competitive day, the equilibrium of marginal valuations and costs. They do not quantitatively reflect the infra-marginal or extra-marginal values, other than in a severely censored sense. We know that infra-marginal values are weakly higher and extra-marginal values are weakly lower, but beyond that one must rely on functional forms for utility or demand to extrapolate. For policy purposes this is generally insufficient to undertake cost-benefit calculations.

When producers are contemplating a new product or innovation, they have to make some judgment about the value that will be placed on it. New drugs, and the research and development underlying them, provide an important example. Unless one can heroically tie the new product to existing products in terms of shared characteristics and somehow elicit values on those characteristics, there is no way to know what price the market will bear. Value elicitation experiments can help fill that void, complementing traditional marketing techniques (see Hoffman et al. 1993).

Many goods and services effectively have no market, either because they exhibit characteristics of public goods or because it is impossible to credibly deliver them on an individual basis. These nonmarket goods have traditionally been valued using surveys, where people are asked to state a valuation “contingent on a market existing for the good.” The problem is that these surveys are hypothetical, in terms of the deliverability of the good and the economic consequences of the response, and this understandably generates controversy about their reliability (Harrison 2006).

It does not follow that subjective values are those that society should use for decisions that have public consequences. For example, when public goods are being provided, the subjective value that is elicited may entail “free riding,” which occurs when one personrationally understates his or her private valuation for the good in the expectation that others, in aggregate, will be willing to pay it. In this case subjective values will understate true values, and society would end up with too little investment in public goods if it relied on consumer sovereignty. We are interested in understanding when the subjective values we elicit are biased in relation to true subjective values. In such settings we may adjust the elicited subjective values in some way.

A related example might be the subjective values that an addict would place on some drug. Even if we elicit the value reliably, it is not obvious that we should use that value when deciding on policy on the drug. In this case society may take a longer-term perspective on the subjective value of the drug, even its subjective value to the addict (e.g., Becker and Murphy 1988). Or it might consider the effects of the addict’s consumption of the drug on others, such as the addict’s family or society as a whole. Consumer sovereignty should not be abandoned lightly, because it constrains politicians and bureaucrats from asserting value in the absence of any “market test.”

PROCEDURES FOR MEASURING SUBJECTIVE VALUES

Direct methods for value elicitation include auctions, auction-like procedures, and “multiple price lists.” Sealed-bid auctions require the individual to state a valuation for the product in a private manner and then award the product following certain rules. For single-object auctions, the second-price (or Vickrey) auction awards the product to the highest bidder but sets the price equal to the highest rejected bid. It is easy to show, to students of economics at least, that the bidder has a dominant strategy to bid his or her true value: Any bid higher or lower can only end up hurting the bidder in expectation. But these incentives are not obvious to inexperienced subjects.

INTERNATIONAL ENCYCLOPEDIA OF THE SOCIAL SCIENCES, 2ND EDITION
A real-time counterpart of the second-price auction is the English (ascending bid) auction, in which an auctioneer starts the price out low and then bidders increase the price to become the winner of the product. Bidders seem to realize the dominant strategy property of the English auction more quickly than in comparable second-price sealed-bid auctions, no doubt due to the real-time feedback on the opportunity costs of deviations from that strategy (see Rutström 1998; Harstad 2000). Familiarity with the institution is also surely a factor in the superior performance of the English auction: First encounters with the second-price auction rules lead many noneconomists to assume that there must be some “trick.”

Related schemes collapse the logic of the second-price auction into an auction-like procedure due to Gordon Becker, Morris DeGroot, and Jacob Marschak (1964). The basic idea is to endow the subject with the product and to ask for a “selling price.” The subject is told that a “buying price” will be picked at random and that if the buying price that is picked exceeds the stated selling price, the product will be sold at that price and the subject will receive that buying price. If the buying price is equal to or lower than the selling price, the subject keeps the lottery and plays it out. Again it is relatively transparent to economists that this auction procedure provides a formal incentive for the subject to truthfully reveal the certainty equivalent of the lottery. One must ensure that the buy-out range exceeds the highest price that the subject would reasonably state, but this is not normally a major problem. One must also ensure that the subject realizes that the choice of a buying price does not depend on the stated selling price; a surprising number of respondents appear not to understand this independence, even if they are told that a physical randomizing device is being used.

Multiple price lists present individuals with an ordered menu of prices at which they may choose to buy the product or not. In this manner the list resembles a menu, akin to the price comparison Web sites available online for many products. For any given price, the choice is a simple “take it or leave it” posted offer, familiar from retail markets. The set of responses for the entire list is incentivized by picking one at random for implementation, so the subject can readily see that misrepresentation can only hurt for the usual revealed preference reasons. Refinements to the intervals of prices can be implemented to improve the accuracy of the values elicited (see Andersen et al. 2006). These methods have been used widely to elicit risk preferences and discount rates as well as values for products (see Holt and Laury 2002; Harrison et al. 2002; Andersen et al. 2007).

Indirect methods work by presenting individuals with simple choices and using a latent structural model to infer valuations. The canonical example comes from the theory of revealed preference and confronts the decision maker with a series of purchase opportunities from a budget line and asks them to pick one. By varying the budget lines one can “trap” latent indifference curves and place nonparametric or parametric bounds on valuations. The same methods extend naturally to variations in the nonprice characteristics of products and merge with the marketing literature on “conjoint choice” (e.g., Louviere et al. 2000; Lusk and Schroeder 2004). Access to scanner data from the massive volume of retail transactions made every day promises rich characterizations of underlying utility functions, particularly when merged with experimental methods that introduce exogenous variation in characteristics in order to statistically condition and “enrich” the data (Hensher et al. 1999). One of the attractions of indirect methods is that one can employ choice tasks that are familiar to the subject, such as binary “take it or leave it” choices or rank orderings. The lack of precision in that type of qualitative data requires some latent structure before one can infer values, but behavioral responses are much easier to explain and motivate for respondents.

One major advantage of undertaking structural estimation of a latent choice model is that valuations can be elicited in a more fundamental manner, explicitly recognizing the decision process underlying a stated valuation. A structural model can control for risk attitudes when choices are being made in a stochastic setting, which is almost always the case in practical settings. Thus one can hope to tease apart the underlying deterministic valuation from the assessment of risk. Likewise nonstandard models of choice posit a myriad of alternative factors that might confound inference about valuation: Respondents might distort preferences from their true values, they might exhibit loss aversion in certain frames, and they might bring their own homegrown reference points or aspiration levels to the valuation task. Only with a structural model can one hope to identify these potential confounds to the valuation process. Quite apart from wanting to identify the primitives of the underlying valuation free of confounds, normative applications will often require that some of these distortions be corrected for. That is only possible if one has a complete structural model of the valuation process.

A structural model also provides an antidote to claims that valuations are so contextual as to be an unreliable will-o’-the-wisp. If someone is concerned about framing, endowment effects, loss aversion, preference distortions, social preferences, and any number of related behavioral notions, it is impossible to generate a scientific dialogue without being able to write out a structural model and jointly estimate it.

VALUES

The word value appears in two forms. The first is as a noun meaning core ideals and norms, as in, for example, “independence is a core value in contemporary U.S. society.” The second form of value is a verb meaning the process by which things acquire importance or economic price, which is sometimes understood as valuation, as in, for example, “the ball was valued at $1.29 for quick resale” or “group members value her participation.” Most social theory has focused on values as nouns that represent key ideas for a given culture, perform certain functions for society, or figure in ideological systems of power. However, an additional consideration of valuation can bring into focus issues of value change and the relationships between cultural and economic values.

Emile Durkheim (1858–1917) articulated a model of society in which social norms and values arose from the increasing specialization of social roles and labor in the emerging industrial societies of the time. Values and norms of behavior provide the social integration that allows individuals to function in society (Durkheim [1893] 1997), providing cohesiveness, trust, and stability. Durkheim’s model of integration provided the background for Talcott Parsons’s mid-twentieth century theory of society, which emphasized the functionality of values and rules, particularly in maintaining the equilibrium and stability of society (see especially Parsons 1951). Culture and a system of values form one of four dimensions of society, the others being social structure, relation to environment, and achievement of goals. For Parsons, the value system must be integrated into people’s personalities and will then guide appropriate behavior. For example, competitiveness and autonomy, or individualism, are key values that are important for people to adopt to be successful in a capitalist economy, and much effort in schooling and media is spent on inculcating those ideals.

This view of values is easily critiqued for its prioritization of system stability over the possibility of social change, and for reducing the scope of agency for individuals who are seemingly programmed by social institutions to adhere to norms and uphold values. While Durkheim’s work on values clearly contributed to the functionalism of Parsons, Durkheim took a view of crime and criminality...
(On the Normality of Crime, 1895) that prefigures more critical approaches to values and norms, particularly what has been known as labeling theory (Becker [1963] 1997), and also critical approaches to deviance, such as those of Michel Foucault (1977). Labeling theory argues that acts are not inherently deviant but are labeled deviant by others, particularly powerful groups that articulate normative systems to protect social stability and their interests. For example, civic unrest may be treated by the state as sign of the deviance of protestors. But unrest may nonetheless hold value as a release for social tension and further may indicate that systematic injustice on the part of the state requires response and remediation and that alternative or neglected values should be given consideration.

Values are thus a part of systems of social power, providing the ideological frame that shapes public discourse about how the social world is operating and how it should operate. For example, when individualism as a value is prevalent, explanations for social troubles are often laid upon the shoulders of individuals: Joblessness is taken as a sign of individual lack of effort rather than diminished regional economy; mental illness as weakness or individual pathology rather than as outcome of stress and conflicting social expectations. Values are associated with and defined by those with the greatest social power. For example, in Western contexts rationality and authority are associated with masculinity, while emotionality and dependence are stereotypically associated with femininity. This means that, for example, female professors may have more difficulty in establishing authority in a classroom: If they engage in conduct considered normal for a male professor, they are seen as breaking gender norms and dismissed as cold or shrill, whereas if their behavior adheres to stereotypically feminine norms of conduct, they are not taken seriously as experts. Other social stereotypes and the values attributed to ascribed characteristics such as race, gender, or attractiveness lead to forms of discrimination both subtle and obvious.

The differential effects of values are thus an issue for formal politics and public policy as well as informal arrangements of social power. While technocracy (rule by experts) has its appeal as a seemingly neutral form of governance, it cannot itself define social priorities and thus still relies upon values to direct the efforts of the state. For example, while scientists may be able to describe the phenomenon known as global warming with mathematical tools with no obvious bias or values, it is still a matter of values to identify the potential social and environmental changes as harmful to human objectives.

Values also intersect with public policy in that negative values used to portray social groups may lead to discrimination and impede more useful ways of addressing problems. For example, groups that value social solidarity and tradition over competitiveness (whether Native American, Amish, or urban African American) come to be seen as having a “culture of poverty” and are blamed for their “backwardness” and lack of economic achievement. Recent research suggests that while values and attitudes are relevant factors, socioeconomic or class background is far more important in shaping potential success in education and work. Specifically, African American families do not possess some pathological set of values that prevents their economic achievement: Income and educational disparities can be attributed to both mechanisms of social reproduction that make it difficult for poor people of any race to achieve intergenerational social mobility and to ongoing processes of racial discrimination that result in lower wages for persons with similar qualifications (Mason 2007).

Because the media continues to circulate social stereotypes and uncritically reflects normative ideologies of value, it has a large role in supporting existing structures of power at the expense of productive social and value change. Whether relying on racial stereotypes or on common narratives of “the self-made man,” television programming reinforces value systems. Media may use representations of deviance to titillate and sell, but this is done with the sense that the actions or characters represented are not normal, and sometimes to make specific points about morality. Most police dramas, whether fictional or “reality”-based, play on this process. Of course, advertisements sell products based on their value, both in the sense of monetary cost and utility, and as representations of larger ideas: Car commercials sell freedom and individualism, household cleaners sell cleanliness and domestic harmony. People in the United States will apparently buy anything that is marketed as “convenient” even if it really is not, or even if it undermines other values such as environmental sustainability or community (Tierney 1993).

As markets continue to globalize, both products and values will travel to new areas. To do this, products need to be legible to consumers. John Evans (1998) argues that processes that simplify and standardize everything, from units of land and property laws, to sizes of clothing and other units of measure, can either be products of state regulation or of capitalist needs for stability and regularity. Values, too, will travel as people learn to want to participate in global economies as producers and consumers. George Ritzer (2004) argues that the need to remove anything controversial and to reduce the identity of consumer products to their “lowest common denominator” to ensure the widest possible sales will strip away all but the most trivial of meanings from commodities and cultural products.
Legibility is a property of things to be read and measured. Its establishment involves a set of processes by which units and systems of notation are formulated and provide metrics for the evaluation of things. These processes also connect issues of law and custom as the economic values of things interact with moral or cultural values. What is the value of a human life and how is it to be measured? Or of a sacred site, or an animal species? Legibility is a form of valuation, which may be tied to economic scales of value established by assessing costs and profits, but also to processes whereby variations in human lifestyles are labeled worthwhile, normal, or deviant. Alternative lifestyles are ineligible and perceived as deviant by the mainstream, as unable to be understood or valued, and are not protected by law (Butler 1993). Legibility and economic valuation are ways of establishing and reading value and measure and are closely intertwined, suggesting that production and consumption and social or cultural reproduction and economic reproduction are more closely intertwined than traditional theories of political economy have suggested (Joseph 1998).

SEE Family Values.

**VANILLA INDUSTRY**

Natural vanilla flavoring is a product of the fruity pods of the vanilla vine, a tropical plant of the genus *vanilla* of the orchid family (*orchidaceae*). There are many varieties, *v. planifolia*, *v. pompona*, and *v. tahitiensis* being the most common. Initially native to the forested highlands of Mexico, vanilla was found in other tropical areas of the globe after its transport to European colonies in Africa and Asia in the sixteenth century by explorers, botanists, priests, and colonial administrators.

The global world market for natural vanilla is approximately 1,000 metric tons, of which the United States is the largest consumer. However, the market for vanilla from vanilla beans is dwarfed by the use of synthetic vanilla, which is well over 95 percent of the total tonnage used in the global flavorings industry and approximately one hundredth of the cost of vanilla from beans. Synthetic vanillin is extracted from cloves and coal tars as well as lignin from paper processing. Although it is a safe flavoring product, vanillin as the signature component of vanilla lacks the subtlety and complexity of natural vanilla, which has additional flavor components and is much prized by home cooks, gourmet chefs, and food processors for which the designation of “real” is important to brand identity.

Vanilla orchids in their native Mexico are pollinated by hummingbirds and a species of small bee. In its other production contexts, this has led to vanilla being one of the most labor-intensive crops in the world, as the orchid flowers must be hand-pollinated to produce beans. Because the flowers last for only one day, farmers must daily tend to their vanilla vines, which are generally looped upon trees that provide shade and protection. Upward of 70,000 small farmers in Madagascar make at least part of their living managing vanilla vines, which can grow to be nearly thirty-five meters in length. There is a three- to five-year time period from transplanting vanilla cuttings or seedlings until the first fruiting, and the healthy maturity of vanilla vines requires effective climbing or trellising supports that provide some shade, adequate rainwater (approximately one meter per year), stable and rich soils, and temperatures remaining above fifty degrees Fahrenheit even at the coldest part of the year. The beans take several months to develop after pollination. They are harvested while green and after harvesting are processed to mature and stabilize the flavors. This ripening process generally takes several months, and the beans are carefully tended by hand.

Until the mid-1980s Madagascar and the islands of Reunion and Córromos off the eastern coast of Africa held a virtual monopoly on natural vanilla production. Mexico’s vanilla market collapsed at the end of the nineteenth century, with political turmoil disrupting produc-
tion, and only began to reorganize in the late twentieth century. The Madagascar cartel controlled an extremely inflated price on the open world market, which provided significant revenues for the government and for exporters. Price controls included export restrictions and the occasional destruction of tons of crops to keep the market price high (as high as US$500 per kilogram). Natural vanilla is a high value–low volume crop, which makes it attractive for biotechnology innovations. Attempts to reproduce natural vanilla through tissue cloning of ripened bean cells seemed to be making progress until new producers, particularly Indonesia and China but also smaller producers such as Uganda, Thailand, Tahiti, and Kenya, broke the monopoly of the Madagascar-based cartel and drove the world market price of vanilla to low levels (as low as US$20 per kilogram). Madagascar remains the largest exporter of vanilla. The world price continues to fluctuate as weather and the emergence of other producing nations interacts with changing demand, but it generally brings about US$50 per kilogram.

The control that the flavor industry maintains in grading and certifying vanilla as real versus synthetic, in labeling laws, and in consumer preferences for natural products are all part of the vanilla industry’s complexity. When natural vanilla prices have been consistently high, there are many more attempts at using biotechnology to produce substitutes, old-fashioned attempts to cut or dilute real vanilla with synthetic vanilla, and ventures for new natural production. Like other botanical products from developing nations, vanilla plants have been a focus of bioprospecting, from taking cuttings out of the country to mapping the genome of valued plants.

Consumer interest in products for which the global commodity chain is used to demonstrate authenticity is part of the new market for vanilla. Knowledge of the origins of a given crop with a particular farmer, through a documented set of links between processors and distributors, adds both cachet and value to vanilla products. Because the small farmers who labor to grow vanilla bear nearly all of the risks of failed crops, decreasing demand, or bad weather yet receive the smallest part of the profits collected by exporters and distributors, there is also a growing interest in fair-trade vanilla. The vanilla orchid is such an environmentally sensitive plant that it fits well into models of ecologically sustainable development. With attention to issues of fair trade and the distribution of risks and profits from vanilla sales, vanilla is sometimes seen as a model for an integrated social and environmentally sustainable production. However, the emergence of multiple small producers in tropical nations that hope to provide revenues for small farmers threatens to again lower the market value of natural vanilla.

VARIABILITY
Variation is one of the most important concepts in quantitative social science research. Associated terms include statistical variation, statistical variability, and dispersion. A dataset containing identical measurements has no variation, whereas a set containing widely dispersed measurements has high variation. There are several different summary statistics that describe, using a single value, the magnitude of the variation (variability) in a set of measurements. In other words, the summary statistics provide a synopsis of the degree to which a set of measurements lacks uniformity.

Among the most popular measures of variation are the range, the mean absolute deviation, the variance, and the standard deviation. Scholars use one or more of these measures to parsimoniously summarize the uniformity of a dataset rather than presenting the set in its entirety because presenting the entire set typically would require too much space and would be inconvenient to examine, particularly when the dataset is large. The disadvantage to using one or more of these summary statistics rather than presenting the entire set is the loss of information. The information loss occurs because summary statistics can be equal across datasets that contain different sequences of numbers. Each summary method attempts to provide important information about the degree to which the set lacks uniformity while minimizing the amount of information lost by not presenting the entire set of measurements. In general, the methods used to describe variability that present more information are more difficult to interpret for those without statistical training.
The measure of variability that most people consider the easiest to interpret is the range, which textbooks often define as the highest number in the set minus the lowest number. More commonly, scholars describe the range as the spread of numbers between the lowest and highest values. The set of numbers \{1, 2, 8, 12, 15\}, for example, has a range of 14, although many scholars would report the range as 1 through 15. Although the range is easy to understand, it is determined only by the two extreme values in each dataset, one or both of which may simply be errors in data entry. For this reason, the range contains less information than alternative variability measures.

Other methods that summarize the degree of variation in a set of measurements provide more information than the range but are more difficult to interpret. These alternatives describe in slightly different ways how far away each number in the set is from the mean of the measurements. The mean absolute deviation (or average absolute deviation) is one such summary statistic. After the range, it is the easiest to calculate and understand. The first step in calculating the mean absolute deviation is to subtract each number in the set from the set's mean. As the name implies, the absolute value of each deviation from the mean is subsequently summed, and the sum is then divided by the number of measurements to produce an average. In the example set \{1, 2, 8, 12, 15\}, the mean absolute deviation is 4.88.

The variance is a slightly more complex summary of variability. The preliminary step to calculating the variance is the same as calculating the mean absolute deviation—determine the distance of each measurement in the set from the set's mean. Subsequently, each deviation is then squared, and the sum of the squared deviation scores is then averaged. The variance of the example number set \{1, 2, 8, 12, 15\} is 29.8. When compared to the mean absolute deviation, the variance places more weight on values further from the mean, while not being as decidedly affected only by the two extreme values that are used to calculate the range. Scholars typically modify the variance formula when attempting to estimate the variance of a population of values based upon the variability of a sample of values drawn from the population. Instead of dividing the sum of deviation scores by the number of values in the sample, the sum of the scores is divided by the number of values minus one. This alteration provides a better estimate of the population’s variance, because the variation observed in a sample of measurements is often less than the variation in the population from which the sample is drawn. For a large set of measurements, however, this added complexity makes little difference. Using this modified formula, the variance of the example number set is 37.3.

The most commonly used measure of variability in scholarly writing is the standard deviation, which is simply the square root of the variance. The standard deviation is typically denoted by the Greek letter sigma (\(\sigma\)) or the abbreviation SD. The standard deviation of the example set \{1, 2, 8, 12, 15\} is 6.1 when the modified formula noted above is used.

Scholars often attempt to explain the variability of one set of measurements (the dependent variable) by considering additional measurements (the independent variables) through the use of more complex statistical methods. For example, we can explain a proportion of the variation in human height by understanding that humans differ in biological sex. This can be visualized by considering that if we calculated the standard deviation of men and women separately, the variability of either group would be less than the overall variability in heights when we do not take gender into account. In other words, because we know that men tend to be taller than women, we can partially explain why the heights of individuals differ. If we wanted to understand more about the variability in human height, we would want to consider factors in addition to biological sex that are associated with height, such as age, parental height, ethnicity, and nutrition. When these explanatory (or independent) variables are found, we say that consideration of the independent variable(s) reduces the unexplained variation in the dependent variable.

Scholars rarely are able to explain all of the variation in any set of measurements, particularly in the social sciences. In fact, in the social sciences it is uncommon to explain more than half of the variation in any variable of interest.

VARIABLES, LATENT

Latent variables are commonly used in the social sciences. Whether it is psychological measures such as depression, or sociological concepts such as socioeconomic status, many variables cannot be directly measured. Factor analysis, latent class analysis, structural-equation models, error-in-variable models, and item-response theory illustrate models that incorporate latent variables.

The basic statistical concept of latent variables analysis is simple. These variables refer to an abstract level of analysis that cannot be directly observed and measured. In order to estimate the numerical values of the parameters from empirical data, we must use observable indicators to link the unobservable conceptual variables. An example of a formative model, the measurement model for socioeconomic status (SES), may make clearer this distinction between conceptually abstract and observable levels of analysis. A researcher may observe the variables income, educational level, and neighborhood as indicators (manifest variables) of SES (latent variable). Latent variable models provide a means to parse out measurement errors by combining across observed variables (using correlations among variables), and they allow for the estimation of complex causal models. Those measurement errors may include faulty respondent memory or systematic errors made in the survey process.

Latent variable analysis is parallel to factor analysis. In modern test-theory models, the relation between the latent variable and the observed score (item responses) is mathematically explicit. The form for the relation is a generalized regression function of the observed scores on the latent variable. This regression function may differ in form—a linear pattern for the factor models and a logistic one for the probabilistic models (Mellenbergh 1994). Researchers should decide whether to treat the underlying latent variable(s) as continuous or discrete. Further discussion can be found in Tom Heinen’s demonstrations (1996).

In psychological studies, researchers may adopt a reflective model rather than a formative model because it is the standard conceptualization of measurement in psychology. This model specifies a pattern of covariation between the indicators, which can be fully explained by a regression on the latent variable. That is, the indicators are independent after conditioning on the latent variable (this is the assumption of local independence). An example of a reflective model in the latent variable of depression may use item responses on items like, “I am sad all the time,” “I often feel helpless,” and “I often feel my life is empty.” In the reflective model of depression, it implies that a depressed person will be more inclined to answer the question affirmatively than a mentally healthy person. In ordinary language interpretation, depression comes first and “leads to” the item responses. In the mathematical term, it implies a regression of the indicators on the latent variable, while in the SES model (a formative model), the relationship between indicators and the latent variable is reversed. In other words, variation in the SES indicators now precedes variation in the latent variable; SES changes as a result of an increase in income and/or education and not the other way around.

In sum, latent variable theory signifies both realism and constructivism. Latent variables of the formative model are more a summary of the observed variables, while a reflective model implies entity realism about the latent variable. A causal implication between observable indicators and the latent variable thus is not a strong assumption. It is suggested that researchers be cautious when interpreting the relation in empirical studies (Borsboom et al. 2003).

VARIABLES, PREDETERMINED

This entry explains when a variable is a predetermined variable and how identification and inference require a variable to be predetermined. In social science, researchers often try to explain a phenomenon or an event using one or more explanatory variables. For example, how much an individual earns can be explained (to some degree) by his or her education level, and how much an individual consumes can be explained by his or her income and wealth. In many cases, a social scientist will formulate a model in which one variable is a function of another variable. For example, the following is a model that relates consumption to income and wealth:

Consumption = $c_0 + c_1 \cdot income + c_2 \cdot wealth

where $c_0$, $c_1$, and $c_2$ are numbers. For example, $c_0 = $10,000, $c_1 = 0.7$, and $c_2 = 0.05$. This model implies that a one-dollar increase of income causes consumption to
increase by $c_1$ (that is, consumption increases by seventy cents if income increases by one dollar). In order to estimate this model, we need to extend the model with an error term. This error term captures variables other than income or wealth. Let

$$Consumption = c_0 + c_1 \cdot income + c_2 \cdot wealth + \varepsilon$$

where the error term $\varepsilon$ is assumed to be uncorrelated with income and wealth. If $\varepsilon$ is assumed to be uncorrelated with income and wealth, then income and wealth are exogenous variables. No correlation means that we cannot use the regressors to predict the error term, that is, $E(\varepsilon|\text{income}, \text{wealth}) = 0$. If all the explanatory variables are exogenous variables, then the coefficients can be given a causal interpretation. Suppose that a social science researcher does not have access to data on wealth and, therefore, estimates the model

$$Consumption = d_0 + d_1 \cdot income + u.$$ 

Note that the new error term $u$ consists of the old error term $\varepsilon$ plus $c_2 \cdot wealth$. Wealth and income are correlated so that income is correlated with $u$. Therefore, we cannot give a causal interpretation to $d_1$. In particular, an estimate of $d_1$ is likely to overstate the effect of income on consumption. Suppose that we have data on consumption and income for $N$ individuals, $\{\text{Consumption}_i, \text{income}_i\}$ where $i = 1, \ldots, N$. Consider the least squares estimator for $d_1$. This estimator minimizes $\sum (\text{Consumption}_i - d_0 - d_1 \cdot \text{income}_i)^2$ with respect to $d_0$ and $d_1$. The least squares estimator for $d_1$ has the following form,

$$d_1 = \frac{\sum (\text{income}_i - \text{mean(income)}) \cdot \text{Consumption}_i}{\sum (\text{income}_i - \text{mean(income)})^2} = d_1 + \frac{\sum (\text{income}_i - \text{mean(income)}) \cdot u_i}{\sum (\text{income}_i - \text{mean(income)})^2},$$

where $\text{mean(income)}$ denotes the mean of income, $\text{mean(income)} = \frac{1}{N} \sum \text{income}_i$. If income and the error term $u$ are uncorrelated, then (1) the expectation of the last term, $\sum (\text{income}_i - \text{mean(income)}) \cdot u_i$, is zero so that $E(d_1) = d_1$, and (2) this last term is very small for large $N$ (the technical term is that $\sum (\text{income}_i - \text{mean(income)}) \cdot u_i$ converges in probability to zero so that $d_1$ is a consistent estimator for $d_1$). However, in this example, the error term $u_i$ depends on wealth. Wealth and income are correlated so that the assumption exogeneity (i.e., that all regressors are uncorrelated with the error term) is violated. As a result, the estimate for $d_1$ cannot be given a causal interpretation. In particular, the expectation of the estimator, $Ed_1$, will be larger than 0.7 because of the positive correlation between income and wealth.

The exogeneity assumption is very strong and can be relaxed somewhat. Consider the following model that describes the squared daily return of a stockmarket (e.g., the daily return of the Standard & Poor’s 500 index),

$$\text{Squared Return}_i = f_0 + f_1 \cdot \text{Squared Return}_{i-1} + \nu_i.$$ 

As before, this model can be extended to include an error term,

$$\text{Squared Return}_i = f_0 + f_1 \cdot \text{Squared Return}_{i-1} + \nu_i + \nu'_i.$$ 

Suppose there are $T$ data points so that $t = 1, 2, \ldots, T$. Rather than assuming that the correlation between the squared return and the error term is zero, that is, $E(\nu_i|\text{Squared Return}_i, \ldots, \text{Squared Return}_{i-1}) = 0$ for all $i$, we now make the weaker assumption that, given the past values of the squared return, the expectation of the error term is zero, that is, $E(\nu_i|\text{Squared Return}_i, \ldots, \text{Squared Return}_{i-1}) = 0$ for all $t$. Note that the past values of the squared return for error term $\nu_i$ consist of the squared return of the first period, $\text{Squared Return}_1$, through period $t - 1$, $\text{Squared Return}_{t-1}$. Regressors that have the property that the error term has zero expectation given past values of the regressor are called predetermined regressors or predetermined variables. Consider the least squares regressor again to see how predeterminedness helps the estimator,

$$f_1 = \frac{\sum (\text{Squared Return}_{i-1} - \text{Squared Return}) \cdot \text{Consumption}_i}{\sum (\text{Squared Return}_{i-1} - \text{Squared Return})^2}$$ 

$$= \frac{\sum (\text{Squared Return}_{i-1} - \text{Squared Return}) \cdot \text{Consumption}_i}{\sum (\text{Squared Return}_{i-1} - \text{Squared Return})^2}$$ 

$$= \frac{\sum (\text{Squared Return}_{i-1} - \text{Squared Return})}{\sum (\text{Squared Return}_{i-1} - \text{Squared Return})^2}.$$ 

The term $\sum (\text{Squared Return}_{i-1} - \text{Squared Return})^2$ is zero in expectation since $E(\nu_i|\text{Squared Return}_i, \ldots, \text{Squared Return}_{i-1}) = 0$. Moreover, for large $T$, this term, as well as $\sum (\text{Squared Return}_{i-1} - \text{Squared Return})^2$, will be small so that the estimate $f_1$ is close to the true value $f_1$. This model of squared returns is an ARCH (auto regressive conditional heteroscedasticity) model and can be used to study volatility. In particular, a large decline of the stockmarket in period $t - 1$ means that the stockmarket will be more volatile in period $t$. Tim Bollerslev, Robert Engle, and Daniel Nelson (1994) discuss other ARCH models.

An endogenous regressor has the property that $E(\nu_i|\text{Squared Return}_i, \ldots, \text{Squared Return}_{i-1}) \neq 0$. Thus, an endogenous regressor cannot be a predetermined regressor. Endogeneity (i.e., having an endogenous regressor) occurs if there is a third unobserved variable that affects both the regressor and the error term. For example,
how much an individual earns can be partly explained by his or her education. Data on earnings and education levels are not hard to collect, but reliable data on intelligence are difficult to obtain. For this reason, earnings are usually regressed on the education so that intelligence is part of the error term. However, intelligence will also affect education levels so that the regressor education and the error term are correlated. In other words, there is an unobserved variable that affects both the regressor and the error term so that $E[y|\text{Squared Return}_1, \ldots, \text{Squared Return}_{t-1}) = 0$. Therefore, least squares cannot be used to estimate the effect of education on income. Econometricians have developed another technique, namely, two-stage least squares.

In nonlinear models, a slightly different definition of exogeneity and predeterminedness is sometimes used. In particular, the regressors are exogenous if the regressors and the error term are statistically independent distributed. That is, if the density of the error term conditional on the regressors, $p(\text{error term}|\text{regressors})$ is the same as the unconditional density of the error term, $p(\text{error term})$. Similarly, the regressors are predetermined if the density of the error term of period $t$ conditional on the past regressors, $p(\text{error term}|\text{regressors}_1, \ldots, \text{regressor}_{t-1})$, is the same as the unconditional density of the error term, $p(\text{error term})$ for all $t$. Robert De Jong and Tiemen Woutersen (2006) use these definitions when they estimate a model to predict monetary policy.

VARIABLES, RANDOM

A random variable is a real-valued function that maps a sample space into the real line. The sample space, denoted by $\Omega = \{\omega\}$, is the set of possible outcomes of some chance phenomenon (e.g., acts of individuals, an experiment). To illustrate, consider the familiar example of tossing a coin. There are only two possible outcomes; hence $\Omega = \{H, T\}$. Here, the symbols $H$ and $T$ are used to denote the outcomes “head” and “tails.” A random variable $Y$ can be defined by setting $Y = 1$ if $H$ occurs, or $Y = 0$ if $T$ occurs. The use of the word “if” here is important; if a coin is actually tossed, “heads” is observed, and $Y = 1$ is recorded, then this value is a realization of the random variable $Y$. The number 1 is not random but is simply a number. The variable $Y$ is considered random unless it is observed. If the coin is “fair,” then the probability that $Y = 1$ (on a toss that has not been observed yet) equals the probability that $Y = 0$; both probabilities equal 0.5. Alternatively, one could also define a random variable $X$, equal to $-1$ if heads occurs, and equal to 1 if tails occurs; in fact, any pair of distinct values could be used to define a random variable describing the outcome of a coin toss.

The concept of random variables was introduced by Pafnuty Chebyshev (1821–1894), who in the mid-nineteenth century defined a random variable as “a real variable which can assume different values with different probabilities” (Spanos 1999, p. 35). The concept is closely tied to the theory of probability, which has been studied since the seventeenth century. However, the modern understanding of random variables and their relation to probability arrived more recently, dating to the work by Andrey Kolmogorov (1933).

Random variables may be either discrete or continuous. In the discrete case, the elements of $\Omega$ are countable, although perhaps infinite in number. In the continuous case, elements of $\Omega$ are not countable, implying that there are infinitely many elements. The elements $\omega$ of $\Omega$ are called elementary events; collections of the elementary events are called simply events.

To formalize the definition of random variables, first consider the case where $\Omega$ contains a finite number of elements. An event $A$ is a subset of $\Omega$, that is, $A \subseteq \Omega$. The complement of $A$ (with respect to $\Omega$) is defined by $\bar{A} = \Omega - A$. Then $\Omega$ is the certain event, while $\emptyset = \Omega$ is the impossible, or null event. Let $\mathfrak{F}$ be the set of all events (including $\Omega$ and $\emptyset$) defined on the sample space $\Omega = \{\omega_1, \ldots, \omega_n\}$; $\mathfrak{F}$ is a field in the sense that it is closed under the formation of unions and complements (i.e., if $A, B \in \mathfrak{F}$ then $A \cup B \in \mathfrak{F}$; if $A \in \mathfrak{F}$ then $A \subseteq \mathfrak{F}$). Then the probability of the event $A \in \mathfrak{F}$, denoted $P(A)$, is a set function onto the closed interval $[0,1]$ satisfying

i. $0 \leq P(A) \leq 1$ for all $A \in \mathfrak{F}$;  
ii. $P(\emptyset) = 1$; and  
iii. $P(A \cup B) = P(A) + P(B)$ if $A \cap B = \emptyset$. 

Tiemen Woutersen
The triple \((\Omega, \mathcal{F}, P)\) is called a probability space.

If \(\Omega\) contains infinitely many elements (either countable or non-countable), \(\mathcal{F}\) is required to be a \(\sigma\)-field, meaning that \(\mathcal{F}\) is closed under the formation of complements and unions of countably many events. In addition, the set function \(P\) must be countably additive so that condition (iii) above becomes

iii. If \(A_1, A_2, \ldots\) are disjoint members of the \(\sigma\)-field \(\mathcal{F}\), then

\[
P\left(\bigcup_{j=1}^{\infty} A_j\right) = \sum_{j=1}^{\infty} P(A_j).
\]

With the preceding concepts, a formal definition is possible. Suppose \((\Omega, \mathcal{F}, P)\) is a probability space in which \(\Omega\) is not necessarily countable. Then a random variable \(Y\) defined on this space is a function mapping \(\Omega\) into the real line such that the set \(\{\omega \mid Y(\omega) \leq y\} \in \mathcal{F}\) for every real \(y\). Hence for each \(\omega \in \Omega\), \(Y(\omega)\) is a real number.

Many examples of random variables appear in the social sciences. Linear regressions involve an attempt to explain the meaning of a continuous random variable; the error term in such equations is a random variable with 0 mean, reflecting statistical noise. Schmidt and Witte (1989) considered the (random, continuous) time that elapses between a criminal’s release from prison and his subsequent conviction for another crime. Nakosteen and Zimmer (1980) examined not only workers’ incomes (continuous) but also their decisions to move to a location (discrete). Others have considered counts of durable goods purchased by households; decisions of graduating high-school students to continue their education in college, enlist in the military, or enter the labor force; and other issues.

BIBLIOGRAPHY

VARIANCE

The variance is a measure of variability among scores. In describing any set of data, one uses three characteristics: the form of the distribution, the mean or central tendency, and the variability. All three are required because they are generally independent of one another. In other words, the mean indicates nothing about the variability.

Variability is a characteristic of all measures. In the social sciences the people or groups that are studied may be exposed to the same treatment or conditions but will show different responses to that treatment or those conditions. In other words, all the scores of the people would be different. The goal of the scientist is to explain why the scores are different. One can think of a score as having two parts: the mean and a deviation from the mean (Hays 1973). If everyone were exactly the same, the variability among scores (deviations from the mean) would be zero.

In manipulating conditions or treatments it is possible to explain different scores between groups by looking at the variability between the groups and also within each group. If the groups are different enough, it is said that they are statistically significantly different. Statistical significance is determined by looking at the probability (odds) that a difference could have occurred by chance. One analyzes the data by looking at the variability of the data and breaking down that variability into its component parts.

There are several methods for measuring variability among scores. The range is the difference between the highest and lowest scores and is limited because it is based on only two scores. It is not very useful because it is influenced easily by extremes among the scores. The mean deviation score sometimes is used as a measure of variability but also is limited in terms of its usefulness in additional mathematical calculations. The standard deviation is used commonly; it is simply the square root of the variance.

The variance is the most useful of these methods. It is defined as the sum of the squared deviations from the mean divided by the number of squared deviations. The equation for the variance is

\[
var = \frac{\sum(X - M)^2}{N},
\]

where \(var\) is the variance, \(X\) is a raw score, \(M\) is the mean of the scores, \(X - M\) represents the deviation of a score from the mean, and \(N\) is the number of scores. Many different symbols have been used to represent the elements of this equation, but in all cases the variance is the average of the squared deviations from the mean.

A simple numerical example can illustrate the variance. There is a small set of five scores: 8, 7, 6, 5, and 4. The sum of those scores is 30, and the mean is 6. The numerator in the variance equation is called the sum of the deviation scores squared (often abbreviated SS for sum
of squares). One takes each score and subtracts the mean (i.e., \(8 - 6 = 2; 7 - 6 = 1; 6 - 6 = 0; 5 - 6 = -1; \) and \(4 - 6 = -2\)). Next, the deviation scores are squared to eliminate the minus signs \((2^2 = 4; 1^2 = 1; 0^2 = 0; -1^2 = 1; \) and \(-2^2 = 4\)). Then one simply adds the deviation scores squared \((4; 1; 0; 1; \) and \(4\)) to get the SS, which is equal to 10. Finally, the variance is calculated by dividing the SS by the number of scores \((N)\), which in this example is \(10/5 = 2\). The variance for this small set of five scores is 2.

This example illustrates an important point: The variance is not a clear indicator of variability. Consider the scores in the example above as inches. The variance is 2 squared inches. How would one make sense out of a variability of squared inches? In the social sciences how would one interpret a variability of squared IQ, conformity, opportunity costs, and so on? The variance has no simple or particularly useful explanation in everyday language or in the technical jargon of the social sciences.

However, the variance is an essential mathematical step in describing parametric variability. The variance has the advantage of being additive, something that is not true for its square root, the standard deviation (Games and Klare 1967). This means that in working with more than one group and looking for a measure of pooled or average variability among the groups, one can add variances. This is done in many inferential parametric statistical tests.

The variance is an essential element of much social science data analysis but is not easily interpretable. The standard deviation, which is the square root of the variance, is used commonly to provide a more readily understandable indicator of variability.

**BIBLIOGRAPHY**

Samuel K. Rock Jr.

**VARIANCE-COVARIANCE MATRIX**

The variance-covariance matrix is a convenient expression of statistics in data describing patterns of variability and covariation. The variance-covariance matrix is widely used both as a summary statistic of data and as the basis for key concepts in many multivariate statistical models.

**VERBAL DEFINITION**

The variance-covariance matrix, often referred to as \(\text{Cov}()\), is an average cross-products matrix of the columns of a data matrix in deviation score form. A deviation score matrix is a rectangular arrangement of data from a study in which the column average taken across rows is zero. The variance-covariance matrix expresses patterns of variability as well as covariation across the columns of the data matrix. In most contexts the (vertical) columns of the data matrix consist of variables under consideration in a study and the (horizontal) rows represent individual records. Variance-covariance matrices may, however, be calculated from any pairwise combination of individuals, measurement occasions, or variables. Even this by no means exhausts the possible covariance matrices that may be considered for a statistical model (see Cattell [1988] for an extensive list of the possibilities involving several dimensions).

**MATHEMATICAL DEFINITION**

If \(k\) variables are assumed in a study and letting \(X\) denote a raw score version of the data matrix and \(\mu_k\) a vector of means for the variables under consideration, the covariance matrix is defined as \(E(xx') - \mu_k\mu_k'\), where \(E()\) denotes the expectation operator. If the columns of \(X\) are centered to a mean of 0, the variance-covariance matrix is more conveniently expressed as \(E(xx')\). Within linear algebra, covariance matrices belong to the class of matrices known as nonnegative-definite symmetric matrices.

**CALCULATION**

The sample covariance matrix can be calculated as \(1/n^*1^*(XX' - \mu_k\mu_k')\) if raw score matrix \(X\) is used, \(\mu_k\) denotes a vector of sample means, and where \(^*\) denotes the transpose operator. If data are expressed in column-centered form, \(x = (X - \bar{X})\), \(\text{Cov}(x)\) is calculated as \(1/n^*x'x\), where \(1\) denotes a \(k\)-column vector of 1s and \(n\) denotes the number of observations. The sample variance-covariance matrix, although efficient, is a biased estimate of population variability. As a result, the estimated population covariance matrix divides by the reciprocal of \(n - 1\) of \(n\). If the \(x\) matrix is further transformed to have a variance of 1 (usually termed \(Z_k\)), the resulting sample \(\text{Cov}()\) matrix is known as a *correlation matrix*. If the \(X\) matrix is retained in raw score form and an additional unit column is added to the data, \(1/n^*x'x\) is referred to as an *average sum of squares and cross-products matrix*, a data summary convenient for models in which overall elevation as well as patterns of covariation are of interest, as often occurs in longitudinal studies of growth.
PROPERTIES
The Cov() matrix has as many rows and columns as the columns of X and is symmetric (meaning that the value associated with the \( j \)th row and \( k \)th column in Cov() is equal to the value in the \( k \)th row and \( j \)th column). Diagonal elements of Cov() represent the variances of the column variables; off-diagonal elements represent covariances or, if based on \( Z_x \), correlation coefficients.

ADDITIONAL MATHEMATICAL PROPERTIES
Covariance of a sum: Assuming three matrices \( x_1 \), \( x_2 \), and \( y \),

\[
\text{Cov}(x_1 + x_2, y) = \text{Cov}(x_1, y) + \text{Cov}(x_2, y).
\]

Covariances involving matrix products: Assuming two conformable matrices \( A \) and \( B \),

\[
\text{Cov}(AX, BX) = A \text{Cov}(X, X) B',
\]

where ' denotes the transpose operator.

USES
As mentioned before, covariance matrices, by themselves, are compact summaries of the variability and covariation present in data. More generally, the covariance matrix and vector of means constitute sufficient statistics for models that assume a multivariate normal distribution. As such, the covariance matrix may be used in lieu of the raw data in calculating a number of multivariate statistical models, such as confirmatory and exploratory factor analysis (assuming the diagonal of the matrix is appropriately adjusted by the estimated communality), path analysis, or other general linear models, including the special cases of multiple regression, analysis of variance, and repeated measures analysis of variance or MANOVA. In many statistical models, finding an optimal basis for representing the covariance matrix in a compact fashion is of primary interest. Such reduced or optimal bases are referred to as principal components analysis (PCA), or in image processing as the Karhunen-Loève transform, which has time series applications within psychology (Molenaar and Boomsma 1987). Covariance matrices alone are not sufficient statistics for other more sophisticated models, such as those involving weighted least squares, sampling weights, or other categorical or distributional adjustments to reflect the dichotomous, polytomous, or other distributional characteristics of the variables under consideration.

VARIATION
Variation refers to the degree of dispersion, diversity, or inequality in a distribution: the extent to which observations of an attribute are similar to or different from one another. Applications of variation in the social sciences include income inequality, the degree to which incomes are concentrated among a few households or spread broadly across a population, and religious diversity, which describes whether a single religion dominates the cultural landscape or multiple religions exist side by side.

COMPONENTS AND MEASURES OF VARIATION
Popular quantitative measures of variation include the following:

- **Range**: The difference between extreme values.
- **Variance**: The sum of the squared distances from each observation to the mean divided by the number of observations (for a population) or divided by one less than the number of observations (for a sample).
- **Standard deviation**: The square root of the variance.
- **Coefficient of variation**: The standard deviation divided by the mean. Graphically the coefficient of variation describes the peakedness of a unimodal frequency distribution. Because the coefficient of variation scales to the mean, this measure often is used in comparative analysis.
- **Gini coefficient**: Bounded by zero and one, where lower values correspond to greater equality, the Gini coefficient is defined as twice the area between the Lorenz curve and an equality diagonal. (To construct a Lorenz curve, one ranks the observations from lowest to highest on the variable of interest and then plots the cumulative

BIBLIOGRAPHY

Variation

proportion of the population against the cumulative proportion of the variable of interest.)

*Theil's T statistic*: Particularly appropriate for hierarchical, nested, or aggregate data, Theil's T statistic is the product of the population share of each observation, the quotient of the observation and the population average, and the natural logarithm of the quotient of the observation and the population average, summed over all observations. Unlike the Gini coefficient and the coefficient of variation, Theil's T statistic is sensitive to the number of underlying observations.

In addition to these widely used metrics, researchers sometimes create original measures to isolate a particular type of variation. For example, in *American Apartheid* (1993), Douglas Massey and Nancy Denton develop five dimensions of variation to identify racial “hypersegregation” in U.S. metropolitan areas.

Whereas measures of central tendency, such as the mean, median, and mode, describe the center of gravity of a distribution, measures of variation express how concentrated the observations are around the average. Both types of measures are necessary to describe most social science data sets. For instance, with regard to the test scores in a school, the median expresses the score of a typical student. Schools desire high median scores. However, a high level of variation in test scores indicates that some students excel, while others lag behind their peers. This could suggest differences among students in family resources, native intelligence, or other characteristics over which a school has little control, but high variation also can result from inconsistent teacher quality or administrative choices to overallocate resources to high-achieving students and/or underallocate resources to low-achieving students.

The ease of computing variation can hide the difficulties in its interpretation. Although variation reflects differences among individuals, it is a property of a group, not an individual. Correlation between variation and another group-level variable does not imply a corresponding relationship across individuals; improperly asserting that it does is an instance of the ecological fallacy. Similarly variation is relative. A measure of variation can only be described as high or low in comparison to the variation of another group, the same group in a different time period, or a predefined standard value.

**USE OF VARIATION IN SOCIAL SCIENCES**

Whether variation in a particular attribute is preferred is an issue of context and perspective. A high degree of variation may be preferable, as in the case of racial diversity within communities, in which variation may imply integration rather than segregation. A low degree of variation may be preferable; for instance, a good medical intervention consistently will improve the health of those who receive treatment and have few side effects. Alternatively, preference for high or low variation may depend on one's theoretical or ethical perspective. For instance, one view of income inequality is that higher levels of variation reflect a more efficient economic system that rewards hard work (or talent) and punishes laziness (or ineptitude). An alternative view is that income inequality suggests nondemocratic use of monopoly power or outright oppression of the poor.

One way to reduce subjective judgment is to view variation as a predictor variable rather than an outcome variable. An example of such an application is research that relates economic inequality to population health. In a 1975 article Samuel Preston popularized this issue by pointing out an inherent nonlinearity in the relationship of health to income. For individuals with low incomes, an increase in economic resources will be accompanied by significant health gains, but as an individual's income rises to the top of the distribution, subsequent increases in income will yield diminishing returns in terms of health. Thus at least among nations with high average incomes, lower variation of incomes should be associated with better health. Although subsequent scholarship seemed to confirm this correlation, there is debate over causation. Some scholars assert that inequality leads to stress and stress leads to poor health. Other researchers point to mediating factors, such as race and access to care, to explain the correlation between inequality and health.

Individuals with low incomes are more likely to have poor health, and individuals with high incomes are more likely to have good health, on average. Thus the suggestion that an increase in inequality that results from the poor getting poorer would decrease population health seems reasonable. However, advocates of the inequality hypothesis also must explain why an inequality increase that occurs when the rich get richer also would reduce health. Until they address this seeming paradox, the burden of proof lies with those who claim that income variation is an operative factor for health. This exemplifies the central challenge in using variation in social science analysis; to be a useful tool, variation must be both measurable and meaningful.

VATICAN, THE

The term Vatican, like the word Washington, has multiple meanings. Geographically, it is one of the Seven Hills of Rome, located west of the Tiber River. Politically, it is an independent state within the city of Rome. Ecclesiologically, it is the bureaucracy that serves the pope in governing the Catholic Church.

With the collapse of the Roman Empire in the West, the people of Italy turned to the Church for leadership when Constantinople was unable to defend them against the barbarian invasions. Even before the Papal States formally existed, popes were raising armies, maintaining public order, and providing government services. By 590, Gregory the Great was the de facto ruler of Italy. With Lombards attacking from the north and a weak and unsympathetic imperial government in the south, Pope Zacharias backed Pepin as king of the Franks. In exchange, Pepin defended Rome and presented the pope with the Papal States in 773. His son, Charlemagne, was crowned in Rome by Pope Leo III in 800, establishing the Church as a major source of political legitimacy in Europe.

For the next 1,100 years, through diplomacy and war, the popes fought to preserve or expand the Papal States, which they saw as the only way to maintain the political and financial independence of the Church in a precapitalistic agrarian society. The power and wealth of the Papal States, however, corrupted the papacy as much as it protected it. The loss of the Papal States in 1870 proved to be an unanticipated blessing for the Church because it freed the papacy to pursue its spiritual goals without having to worry about governing 16,000 square miles of Italy. The normalization of relations between the Vatican and Italy in 1929 left the pope with 108.7 acres.

Under international law, the Vatican is a sovereign state headed by the pope, who has supreme legislative, executive, and judicial authority. It has its own army (Swiss Guard), flag, passports, stamps, post office, Internet domain extension (.va, as in vatican.va.), and the right to mint a limited number of coins. Criminals are normally turned over to Italy for prosecution and punishment. Citizenship is given on a temporary basis to about 500 people working for the Vatican, about half of whom are members of the Vatican diplomatic service. Another 100 are members of the Swiss Guard. The governance of Vatican City is delegated to the Pontifical Commission for the Vatican State (five cardinals), which is headed by a cardinal president appointed by the pope. Under the president, a lay delegate acts as a city manager and runs the day-to-day affairs of Vatican City, which employs about 1,300 people for administration, maintenance, police, stores, and its world-class museums. The Vatican City budget is normally in the black even though it has no taxes because of income from the museums, post office, supermarket, gasoline station, and other stores.

Located in the Vatican is the Instituto per le Opere di Religione, commonly known as the IOR or Vatican Bank, founded in 1887 after the fall of the Papal States as a way of keeping Vatican finances independent of Italian control. Its depositors are now limited to the Vatican agencies, Vatican employees, dioceses, religious orders, and other Church entities. Although in the past some depositors used it to launder money, since 1993 the bank has cooperated with police investigations. Like any bank, it invests its deposits; the profits are used at the discretion of the pope. Its involvement in one investment scandal caused it to pay $244 million to Banco Ambrosiano creditors. This scandal led to the reform of the bank, which is now governed by a committee of cardinals whose principal function is to select a supervisory council of financial experts from around the world to supervise the bank and hire its lay director-general. No financial report is made public.

The Vatican Curia is the bureaucracy that helps the pope in his ministry as head of the Catholic Church (he has a separate bureaucracy for the diocese of Rome). The oldest bureaucracy in the world, it is shaped more by history than organizational theory and still has many of the trappings of a medieval court. It has about 2,500 employees. The professional staff (mostly priests) is recruited from all over the world, but the support staff is mostly Italian. It is financed by donations and income from investments. The official language is Latin, but the working language is Italian. Most offices have people who can communicate in the other major European languages.

The top official under the pope is the secretary of state, who is more like a prime minister than a U.S. secretary of state. The secretary of state has two offices: the
First Section for General Affairs, headed by the sostituto (substitute), and the Second Section for Relations with States, headed by the secretary for relations with states. Although there are numerous exceptions, the principal work of the First Section is internal Church affairs, while the Second Section deals with international issues. Both sections are relatively small; for example, the Second Section has only about forty people.

The First Section is divided into language desks, with the sostituto acting as the pope’s chief of staff. Practically all paper going to and from the pope goes through this office, making the sostituto one of the most powerful men in the Vatican, although he is not a cardinal.

The Second Section, divided into country desks, is the Vatican’s foreign ministry, with the secretary acting as the foreign minister. Practically every nation in the world sends an ambassador to the Holy See (the major exception is China). The Vatican stresses (and legal scholars agree) that diplomatic relations are with the Holy See and that the pope would have the right to them under international law even if the State of Vatican City (Stato della Città del Vaticano) ceased to exist. Vatican foreign policy has supported international cooperation through the United Nations, the peaceful resolution of international disputes, human rights, disarmament, and aid to refugees and poor countries, while opposing international financing of abortion. But its principal concern is the promotion of religious freedom and the good of the Church. Historically it has attempted to protect the rights of local churches through international treaties (concordats) with countries.

Other dicasteries (offices) of the curia are organized as congregations or councils. They are committees of prelates (some working in Rome, others heading dioceses around the world), which meet under the leadership of a prefect (for congregations) or president (for councils). The prefects and presidents also head the staffs of their congregations and councils, which do the day-to-day work of the curia. The older congregations tend to deal with internal Church affairs: doctrine, liturgy, Eastern (non-Latin) Catholic churches, canonization of saints, appointment of bishops, evangelization, clergy, members of religious orders, and Catholic education. The newer councils are a mixed bag of offices dealing with issues that have concerned the Church since Vatican II: laity, ecumenism, family, justice and peace, health-care workers, canon law, communications, culture, and interreligious dialogue. Most staffs are quite small. They relate to Catholic dioceses around the world either directly or through the Vatican diplomatic representatives (nuncios) in each country.

The Congregation for the Doctrine of the Faith (formerly the Inquisition) is the most powerful office. It must review and approve the doctrinal content of documents from other offices before publication. It also attempts to control the teaching and writing done by Catholic theologians around the world. The congregations for bishops and evangelization of peoples propose names to the pope for episcopal appointments around the world, in a process that screens for orthodoxy and loyalty to the pope.

From at least the time of Constantine, the papacy has been an instrument of political legitimacy in Europe. This has given the Church political power, which it often used for good—to mediate disputes, insist on the observance of law, and protect the powerless—but sometimes used for evil—to suppress heresy and enrich itself. This power and wealth, however, made it a target of political intervention, whether imperial, feudal, or totalitarian. Beginning with Leo XIII in the nineteenth century, the Church began developing a social teaching that was more appropriate for a pluralistic democratic world. The contemporary political role of the papacy was epitomized in John Paul II (1920–2005), who through his support of Solidarity and the Polish freedom movement began the landslide that wiped out communism in Eastern Europe and ultimately the Soviet Union. He was also an outspoken defender of religious freedom, human rights, refugees, migrants, the environment, and the unborn. He spoke of the responsibility of the rich to help the poor and advocated forgiveness of Third World debt. He opposed both Persian Gulf wars. He was critical of unbridled capitalism and a culture of individualism, greed, and consumerism. Although lacking the political skills of John Paul, Benedict XVI (b. 1927) has not strayed far from his foreign policy positions.

Papal opposition to birth control and abortion have been controversial. While most Catholic moral theologians oppose abortion, a number consider making it illegal a debatable issue. John Paul did not shrink from giving Communion to pro-choice Italian politicians, although this became an issue for a few U.S. bishops in 2004. Most theologians, priests, laypeople, and even some bishops do not accept the pope’s teaching on birth control, with the result that many Catholic countries such as Italy and Spain now have falling birthrates. Also controversial both inside and outside the Church has been the questioning of condoms as a means of fighting AIDS. This dissent on Church teaching led the Vatican to investigate, reprimand, and silence many priest theologians. It also led to the appointment of bishops known for their loyalty and support for Church teaching. But with the exception of abortion, birth control, and condoms, the Vatican’s position of international issues has been far to the left of most American politicians.

**VEBLEN, THORSTEIN**

1857–1929

Thorstein Bunde Veblen, an economist and sociologist (social critic and social and cultural theorist), was born to a Norwegian immigrant couple and grew up in rural Minnesota. He attended Yale University for graduate work in philosophy, where he met the sociologist William Graham Sumner (1840–1910). Upon graduation Veblen was not able to find academic employment. He eventually went to Cornell University to study economics, then taught at the University of Chicago (1891), later moving to Stanford University (1906), the University of Missouri (1911), and the New School for Social Research (1919). Veblen's troubles with university administrations stemmed from his disregard for the norms of dress for "proper professors," his uncommon living conditions (he lived in a shack of his own construction at one point), his classroom presentations (he often spoke softly in monotone or displayed unorthodox behavior), and his unconcealed extramarital affairs. At one point in his career he taught a class entirely in the Icelandic language to make the point that modern education was useless. Veblen saw himself as outside both Norwegian and American cultures and specifically asked those who knew him not to write his biography after his death.

Veblen posited certain human instinctual drives (mediated by cultural norms) that allow for technological and social advance, social organization, and social evolution: the instinct of workmanship, which is the most productive instinct for well-being, being an underlying creative impulse to manipulate the world with productive labor; the instinct of parenting, which leads to a concern for the well-being of others and an identification with community; and the instinct of idle curiosity, which leads to the development of knowledge. His use of the word *instinct* does not correspond to standard understandings from biology. Rather, he used *instincts* as socially refracted modifications of desire (Veblen 1914).

**SOCIETY**

Influenced by Darwin’s theory of evolution, Veblen was interested in the historical and evolutionary development of society and argued that humans interpret the world using categories based in biographic and historically shaped "habits of the mind," which in turn are the basis for cultural norms passed on through socialization. Activities formed around these norms Veblen called “institutions,” with changes in productive activity leading to changes in society (Veblen 1914).

Veblen formulated a scale of three evolutionary stages of society based on changes in material forms of production: “savagery” (a peaceable, isolated, and stable society); “barbarianism” (a warlike and conquest-oriented society, hierarchical and dominated by religion, with distinct predatory and industrious classes and a surplus of wealth); and "civilization" (a modern, economically developed society that is rational and instrumental, with machine technology, mass production, and a high division of labor). For Veblen, the business class in modern society is “predatory” in that its livelihood is based on the acquisition of personal wealth and competitive capitalist profit making (Veblen 1914). In other words, Veblen labeled modernity as a form of latter-day barbarism.

Veblen is most famous for his book *The Theory of the Leisure Class* (1899), which some view as a satire of American elite society but others interpret as a “coded” social criticism that was a product of his marginal social status (Riesman 1995). In either case, it establishes Veblen’s commitment to the idea that culture shapes economics, and as opposed from Marxist-derived, where Marx thought economics shaped society, it is an alternate analysis of society based on an understanding of production and consumption, material life, and economic stratification. In it Veblen shows the social and cultural causes and effects of economic changes (or economic evolution) and includes class, gender, and ethnicity in his economic analysis. He uses a materialistic approach in that he analyzes the changes in habit of productive activity.

Veblen’s social analysis draws a distinction between two classes of people. The first, the privileged, elite class of businesspeople and captains of industry, survive through the parasitic exploitation of the productive class and engage in pecuniary activities that detract from the further evolution of society. This is his critique of capitalism, which includes an attack on industrialists he labeled as “robber barons.” Veblen viewed this class as militant and
predatory because its members do not engage in productive work; instead, they live off of the innovations of other people. The second class, made up of industrious workers, engineers, and inventors, produces both the wealth and useful goods for society. This class is focused on the well-being of society as a whole and includes women. Veblen tended to associate predatory culture with patriarchy and peaceful, productive culture with women—in this sense, David Riesman regards Veblen as an early feminist. In a capitalistic society within an economic price system, individuals are rewarded not for creative entrepreneurship but for ideals of competition, which for Veblen leads to “sabotage” rather than the advancement of the ideals of production (Veblen 1921). Hence Veblen critiques modernity as latter-day barbarism because of the wastefulness of capitalistic production (Veblen 1904).

For Veblen, competition exists within society due to individuals’ fear of loss of self-esteem. Patterns of consumption and conduct are seen as having symbolic significance and the latent function of enhancing status—Robert K. Merton (1910–2003) drew upon Veblen when writing about manifest and latent functions (Merton 1957). Veblen provides a theory about how individuals symbolize their own social status in the struggle for competitive advantage. Heightened self-evaluation comes with conspicuous consumption, conspicuous leisure, conspicuous waste, and conspicuous display of symbols that indicate high status, all of which are used to communicate social position and improve social standing. Conspicuous leisure indicates elite status and must be expensive because it is a symbolic message that one is above laboring. Conspicuous consumption and waste, demonstrated by the socially visible consumption and display of expensive items, fashion, exotic pets, and so on, also sends the message that one does not participate in productive labor; thus the more wasteful a person is, the more prestige he or she has. Lower-status groups emulate higher-status practices in an attempt to increase their own status, and Veblen calls these habits of competitive display and consumerism wasteful.

Veblen argued that women are exploited by men through vicarious conspicuous consumption, waste, and leisure; that is, the conspicuous activity is performed by the female to benefit the status of the male. Ideals of feminine beauty (e.g., frailty, weakness, and paleness, indicating inability to labor), certain restrictive fashions that prevent laboring, and the removal of women from socially visible, productive labor enhance the status of the male and the good name of the household and its master.

ECONOMICS
In The Theory of Business Enterprise (1904) Veblen gives an account of the business enterprises of the 1900s, with a theoretical analysis of the large-scale corporation and the institutions of U.S. capitalism. This analysis highlights the associations of business and industry, the making of money and the making of goods, ownership and technology, pecuniary and industrial employment, and the roles of those who perform social functions versus those whose behavior leads to waste. Veblen highlights the individual businessperson, the powers he or she holds and what he or she can accomplish with those powers, and his or her effect on the economic and social community as a whole. Veblen looks at the world community as it enters into the industrial age, which is dominated by what he calls the “machine process,” and shows the importance of machines and their relation to business enterprise. This discussion is important for modernization theory. Interestingly, The Theory of Business Enterprise links stock market valuation to aggregate investment in the economy, prefiguring James Tobin’s Q model.

In Absentee Ownership (1923) Veblen attempted to explain U.S. business after World War I (1914–1918) and before the Great Depression, providing a theoretical analysis of absentee ownership and credit and the economic circumstances associated with economic growth and change through the late nineteenth century. He discussed the rise and fall of the captains of industry and the notion of sabotage associated with entrepreneurs.

Finally, in his essays on education Veblen argues that universities, colleges, and even elementary schools increasingly fall under the spell of predatory habits drawn from the business world. Even in the era in which he lived, he found trends such as the increase of administrative expense over funds devoted to teaching, competition and rating among teachers based upon business models of productivity, the rivalry among universities as if they were corporations based upon the profit motive, and so on. He regarded all these trends as the opposite of what education should represent, namely, “idle curiosity”—interest in knowledge for its own sake, not for profit.

WAR, PEACE, AND NATIONALISM
In The Nature of Peace (1917) Veblen looked at the material conditions necessary to induce modern warfare as well as the varied meanings of patriotism within modern society. He saw militarism, nationalism, and patriotism as “predatory” in that they do not benefit the well-being of society as a whole, and he was concerned about military conflict and the patriotic exploitation of the industrial class.

In both Imperial Germany and the Industrial Revolution (1915) and The Nature of Peace (1917) Veblen developed the ideal-type of the “dynastic state” to describe Germany’s and Japan’s hierarchical organization and identification combined with the subservience of their underlying populations. This situation, he argued, results in militant aggressive nationalism and finally war; indeed, he...
criticized nationalism itself because it involves honor and prestige and is therefore barbaric. Veblen used a historical comparison of Germany and Great Britain before, during, and after the Industrial Revolution to show the difference in their developments due to history and context that focused on material causes as well as social-psychological states, and he claimed that when a culture industrializes more rapidly, the country will use this industrialization to produce weapons because of the honor and prestige in being warlike. Militarism is barbaric because it enforces the values of obedience and is obsessed with honor and prestige. Hence if a nation becomes militaristic, this is a sign that it is crossing the border to barbarianism, where war is a natural outcome.

VEBLEN AS CULTURAL THEORIST
Veblen has been interpreted as a cultural theorist, most recently by Stjepan G. Mestrovic (2003) in his analysis of narcissism as central to understanding the unifying strand in Veblen’s approach to culture. Others have used Veblen’s ideas in cultural theory as well. For example, Riesman integrated Veblen’s thought with his own concept of marginal differentiation by the other-directed type and the striving for status by the inner-directed type (Riesman 1953). Riesman and Jean Baudrillard are influenced by Veblen’s idea that all forms of waste must be “conspicuous,” which is to say reflected in the opinions of the mass media and the peer group. These insights led to Riesman’s concept of “fake sincerity,” performed to gain approval from others, and eventually to Baudrillard’s notion of simulacra. The doctrine of separate spheres widely used in feminist theory, the notion of public versus private, was challenged by Veblen’s connection of social spheres through consumerism and status, reflecting a cultural whole with causally linked underlying economic and social class realities (e.g., domination, production, and consumption). Thus Veblen provided an opportunity to understand culture in terms of economics and vice versa. Perceived status and hierarchical social distinctions make status comparisons and symbolic representations central to Veblen’s theorizing.

Veblen had a particular influence in the social sciences with his symbolic representation of social class and social position, use of modernization theory, and analyses of economics (production, consumption, technology, business and industry, and economic growth and change). Veblen’s influence is wide-ranging. C. Wright Mills used Veblen’s work to develop his own ideas about leisure and social status in White Collar (1956) and updated Veblen’s theory of the dominant sociopolitical elite (the predatory business class) in The Power Elite (1956). Chris Rojek incorporated Veblen’s work into leisure studies with his analysis of leisure as taking on the characteristics of work (Rojek 1994), and Theodor Adorno used Veblen when discussing the aesthetics of ostentatious display. The French postmodern Baudrillard developed his own consumption theory concerning the significance of objects and images of consumption in designating prestige, where consumption and leisure should not be understood only as pleasure but also as a ranking and classification system of status itself.

SECONDARY WORKS

Ryan Ashley Caldwell
Vector Autoregression

Vector autoregression (VAR) models were introduced by the macroeconometrician Christopher Sims (1980) to model the joint dynamics and causal relations among a set of macroeconomic variables. VAR models are useful for forecasting. Consider a univariate autoregressive model—for example, an AR(1) \( Y_t = \alpha + \beta Y_{t-1} + \varepsilon_t \)—which describes the dynamics of just one random variable \( Y_t \) (i.e., national income) as a linear function of its own past. Based on this model, the forecast of national income will depend just on its past history. However, economic variables such as national income, employment, prices, money supply, interest rates, and so on interact with each other. For instance, movements in interest rates affect the level of employment, which in turn affects the level of national income. In this multivariate setting, the forecast of national income will be a function of a larger information set that combines not only the history of national income but also the histories of many other variables, such as interest rates and employment. A VAR is the generalization of the univariate autoregressive model to a vector of economic variables.

**DEFINITION**

An \( n \)-variable vector autoregression of order \( p \), VAR(\( p \)), is a system of \( n \) linear equations, with each equation describing the dynamics of one variable as a linear function of the previous \( p \) lags of every variable in the system, including its own \( p \) lags. A simple case is a VAR(2) \( (p = 2) \) for a vector of two variables \((n = 2)\), say \( \{ Y_t, X_t \} \):

\[
\begin{align*}
Y_t &= \alpha + \beta_{11} Y_{t-1} + \beta_{12} Y_{t-2} \\
&\quad + \gamma_{11} X_{t-1} + \gamma_{12} X_{t-2} + \varepsilon_{1t} \\
X_t &= \alpha_2 + \beta_{21} Y_{t-1} + \beta_{22} Y_{t-2} \\
&\quad + \gamma_{21} X_{t-1} + \gamma_{22} X_{t-2} + \varepsilon_{2t}
\end{align*}
\]

(1)

The **innovations** are assumed to be zero-mean random variables, \( E(\varepsilon_{1t}) = E(\varepsilon_{2t}) = 0 \), with constant variance, \( \text{var}(\varepsilon_{1t}) = \text{var}(\varepsilon_{2t}) = \sigma^2 \), possibly correlated, \( \text{cov}(\varepsilon_{1t}, \varepsilon_{2t}) = \sigma_{12} \neq 0 \), and with normal probability density functions.

The components of the definition are:

1. The \( n \)-dimension of the vector: number of variables to model, which is equal to the number of equations in the system.
2. The \( p \)-lag structure: identical number of lags for each of the \( n \) variables in the right-hand side of each equation.
3. The **linear** autoregressive specification.

4. The assumptions on the statistical properties of the innovations.

The joint dynamics are captured in two ways: (1) each variable is explained by the past history of every variable—\( Y_t \) is a function of its own past and the past of the other variables in the system \( \{ Y_{t-1}, Y_{t-2}, \ldots, Y_{t-p}, X_{t-2}, \ldots, X_{t-p}, \ldots \} \); and (2) the innovations may be contemporaneously correlated, that is, \( \sigma_{12} \neq 0 \).

**ADVANTAGES**

*Easy implementation.* Since every equation in the VAR has the same number of variables on the right-hand side, the coefficients \( \{ \alpha_1, \alpha_2, \ldots, \beta_{11}, \beta_{12}, \ldots, \gamma_{11}, \gamma_{12}, \ldots \} \) of the overall system are easily estimated by applying ordinary least squares (OLS) to each equation individually. The OLS estimator has the standard asymptotic properties. In large samples, the OLS estimator is consistent and asymptotically normal distributed.

*Classical inference.* Since the OLS estimator has standard asymptotic properties, it is possible to test any linear restriction, either in one equation or across equations, with the standard \( t \) and \( F \) statistics. Suppose that one is interested in whether the second lag is relevant in the first equation. One writes the null hypothesis as \( H_0: \beta_{12} = \gamma_{12} = 0 \). This is a restriction involving only the first equation. It is also possible to test for restrictions involving more than one equation. Suppose that one is interested in whether the coefficients corresponding to \( Y_{t-2} \) are identical across equations, that is, \( H_0: \beta_{12} = \beta_{22} \). In both cases, an \( F \)-statistic will be appropriate.

The lag length \( p \) is also chosen by statistical testing or by minimizing some information criteria. Suppose that one starts by assuming \( p = 2 \). One writes the null hypothesis as \( H_0: p = 2 \) against an alternative hypothesis \( p > 2 \), say \( H_1: p = 3 \). The VAR model is estimated under the null and under the alternative, and testing is carried out by constructing either the \( F \)-statistic (based on the comparison of the sum of squared residuals for the restricted and unrestricted specifications) or an asymptotic likelihood test (based on the comparison of the value of the likelihood function for the restricted and unrestricted specifications).

*Testing for Granger causality.* It is of interest to know whether one or more variables have predictive content to forecast the variable(s) of interest. For instance, in system (1) one could ask whether \( X \) is helpful in predicting \( Y \). The corresponding null hypothesis is that all the coefficients on the lags of \( X \) are zero, that is, \( H_0: \gamma_{11} = \gamma_{12} = 0 \). If these coefficients are statistically zero, one says that \( X \) does not Granger-cause \( Y \) or, equivalently, \( X \) does not have any predictive content to forecast \( Y \). The null hypothesis can be tested with a standard \( F \)-statistic.
Impulse-response function and variance decomposition.

An important use of VAR is to quantify the effects over time of economic policy. Suppose that the monetary authority shocks interest rates. The questions become: When, for how long, and how much does the shock to interest rates impact employment and output? Impulse-response functions are designed to answer these questions. An impulse-response function describes the response over time of each variable in the VAR to a one-time shock in any given variable while keeping all others constant. For the system described in (1), one has four impulse-response functions: the impact and future effects on $Y$ and on $X$ of a unit shock to $\epsilon_{1t}$, and the impact and future effects on $Y$ and on $X$ of a unit shock to $\epsilon_{2t}$.

Closely associated with the impulse-response function is the variance decomposition. This decomposition refers to the contribution of each innovation to the variance of the forecast error associated with the forecast of each variable in the VAR. Standard time series software provides both impulse-response functions and variance decomposition.

SHORTCOMINGS

Ad hoc specification. VAR models are criticized because they do not shed any light on the underlying structure of the economy. Though this criticism is not important when the purpose of VAR is forecasting, it is relevant when the objective is to find causal relations among the macroeconomic variables. A structural VAR is a system of simultaneous equations that aim to analyze causal relations. For each variable in the system, there is an equation that accounts for simultaneous as well as dynamic interactions among the full set of variables. A structural VAR(2) for \{ $Y_t$, $X_t$ \} corresponding to the system described in (1) looks like:

$$Y_t = a_1 + b_1 X_t + \phi_{11} Y_{t-1} + \phi_{12} Y_{t-2} + \nu_{1t}$$
$$X_t = a_2 + b_2 Y_t + \phi_{21} Y_{t-1} + \phi_{22} Y_{t-2} + \nu_{2t}$$

(2)

where $\nu_{1t}$ and $\nu_{2t}$ are known as the structural innovations. With matrix algebra, it is possible to solve for \{ $Y_t$, $X_t$ \} in the structural VAR. The solution is known as the reduced form, which is the VAR in (1) subject to some parameter restrictions. The question becomes: Is it possible to recover the structural parameters from the estimated parameters of the reduced form? This is known as the identification problem. The structural VAR in (2) has fourteen parameters (twelve coefficients and the variances of the two innovations, assuming that the covariance is zero), while the VAR in (1) has thirteen parameters (ten coefficients, two variances, and one covariance of the innovations). To uniquely identify the structural parameters, the investigator needs one restriction on the structural VAR. Which restriction should be used?

Identifying restrictions. This is a point of debate in structural VAR modeling. The ideal view is that economic theory should dictate which restrictions to impose. However, Sims argued that economic theory was not informative about the appropriate identifying restrictions, and therefore the estimation of the reduced form was the most that one could accomplish. Some researchers impose restrictions on the coefficients of the contemporaneous variables (Sims 1980). Others impose restrictions on the covariance of the structural innovations (Hausman, Newey, and Taylor 1987), or on the long-run multipliers (Blanchard and Quah 1989).

The most popular identifying restriction is the recursive parameterization or lower triangularization of the matrix of contemporaneous coefficients. In the structural VAR(2) described in (2), this restriction is $b_1 = 0$, which implies that exogenous shocks to $X$ will not contemporaneously affect $Y$. If $X$ is money and $Y$ is output, the restriction $b_1 = 0$ means that a shock to the money supply will not affect output instantaneously, though it will affect output with some delay depending upon the dynamics specified in the VAR model. The lower triangularization is the most popular restriction in the time series computer packages.

Ordering of the variables. When the innovations \{ $\epsilon_{1t}$, $\epsilon_{2t}$ \} are contemporaneously correlated, the impulse-response functions will depend on the ordering of the variables. A common solution is to transform the innovations (for instance, using the Cholesky decomposition) such that the transformed innovations are uncorrelated. The implication is that now one can trace the response of the system to an innovation shock in isolation without disturbing the rest of the innovations. The transformation also has implications for the specification of the system because now the first equation will have only one current innovation, the second equation will have two current innovations, the third equation will have three, and so on. Therefore, the ordering of the variables matters. There are no rules on how to choose the ordering of the variables. Economic theory may shed some light, but eventually the choice of the ordering will depend on the questions that the forecaster aims to answer.

VECTORS
It is well known that any point in the plane can be represented by a pair of numbers, its coordinates. If one draws a horizontal axis, labeled the x axis, and a vertical axis, labeled the y axis, then one can represent any point uniquely by giving its x coordinate and its y coordinate in order. Point \((a, b)\) is the point that lies directly on a vertical passing by the point marked \(a\) on the x axis and on level with the point marked \(b\) on the y axis. Naturally, \(a\) or \(b\) can be negative. Note that the order of the coordinates is important. Points represented by \((a, b)\) and \((b, a)\) are not the same (unless \(a = b\)).

There is a complete correspondence between geometrical objects, namely, points of the plane, and purely algebraic objects, namely, ordered pair of numbers. Such algebraic objects that correspond exactly to points are called vectors. Thus a vector is a pair of any numbers \((x, y)\). More precisely, one should call such pairs two-dimensional vectors because the concept can be easily generalized to \(n\)-dimensional vectors, geometrical representation being of course limited to three-dimensional space; nonetheless, the illustrations herein are limited to two-dimensional space.

Economic applications of vectors are quite important and numerous. The presentation herein deals with consumption first, production and activity analysis second, and then finally, temporal processes.

Consumption structures can be easily presented using vectors. The consumption of consumer \(C_i\) consists of \(n\) different quantities or bundles of different commodities (meat, bread, beer, tea …), represented by \(C_i = (c_{i1}, c_{i2}, \ldots, c_{in})\). When for simplicity of presentation one deals with two commodities, then \(n = 2\) and \(C_i = (c_{i1}, c_{i2})\), which can be represented with quantities consumed on relevant axes, as in Figure 1. The length of the vector represents the level of consumption, and its slope represents the structure of composition. Level changes of the “consumption basket” will be represented by an increase or a decrease of the vector length; changes in structure, depending on consumer preferences, revenue, and market prices, will modify the vector slope.

Vector analysis can also be useful to present problems of accumulation with heterogeneous capital goods, a technique dating as far back as Karl Marx’s analysis of “production schemes” found in the second volume (1885) of Das Kapital. John von Neumann (1946) and Wassily W. Leontief (1941) have contributed important modern examples of this technique.

For an example of a production analysis, one might begin by defining an “activity,” “process,” or “production method” representing production of one commodity, say “corn,” using labor, iron, and corn (for seed needs). For one unit of labor time (one hour, one day, or labor time available in the economy), one can obtain a given amount of corn, called \(b_{i1}t\), using \(a_{i1}\) amount of corn and \(a_{21}\) of iron. Consequently, activity can be represented by vector \(OM_t\) (see Figure 2). The first coordinate of \(M_t\) is \(b_{i1} - a_{i1}\), representing “net” production of corn, that is, “gross” production of corn \(b_{i1}\) less intermediate consumption of corn \(a_{i1}\)—the seeds; the second coordinate, \(a_{21}\), represents the intermediate consumption of iron; vector \(OM_t\),
representing the “net product” of activity (1), can be easily constructed by vectoral summation of, first, gross production of corn represented by vector \( O\hat{a}_{11} \), and second, \( D \), vector \( O\hat{M}_1 \), itself sum of inputs of corn and iron.

In a similar way, let iron be produced by another activity producing \( b_{22} \) units (tons ...) of iron using \( a_{22} \) units of iron, \( a_{12} \) units of the other commodity (corn here in this very simplified model), and one unit of labor. Vector \( O\hat{M}_2 \) represents the “net product” of this activity.

One may note that \( O\hat{M}_1 \) and \( O\hat{M}_2 \) have just one positive component, both activities being “specialized” in the production of one and only one commodity. Such a case is called “simple production”; but one may have a different case in which one activity produces two commodities simultaneously (say, wool and milk); in such a case, named “joint production,” both coordinates of \( M_3 \) may be positive, as indicated in Figure 2 (this vector is shown only for mathematical illustration as it is quite difficult to imagine a method producing jointly iron and corn).

When both activities are specialized, one comes to matrix representations such as:

\[
A = \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix}, \quad B = \begin{bmatrix} b_{11} & 0 \\ 0 & b_{22} \end{bmatrix}
\]

which are square matrices largely used in input-output systems, or Leontief models—\( 2 \times 2 \) in the simplified model used here, but \( n \times n \) in a more general treatment. The \( \hat{f}_{i_0} \) column vector represents conditions of production of the \( i_{0} \) commodity (production of \( b_{i_0} \) units of commodity \( i \) necessitates intermediate consumption of \( a_{i_1} \) units of itself and \( a_{i_2} \) units of second commodity, and so on); the \( \hat{f}_{i_1} \) line vector represents utilization of the \( i_{0} \) commodity by the entire system, as intermediate consumption (\( a_{i_1} \) representing intermediate consumption of first commodity by the first production process, \( a_{i_2} \) intermediate consumption of the same commodity by the second production process, and so on).

Von Neumann models are more complicated and more general. First, there is the possibility of joint production. Second, the matrix may be rectangular because there is the possibility of production systems with unequal quantities between the numbers of processes (line vectors) and commodities (column vectors).

It should be noted that when economic systems can be characterized by a “square matrix,” one can define and characterize eigenvectors that have a special structure associated with matrix characteristics. Such vectors play a special role in economic analysis because they can be useful to characterize, on the one hand, special accumulation regimes—with maximum uniform growth rates—and, on the other hand, special price systems—with minimum uniform interest rates.

Vectors can also be useful in presenting and generalizing about temporal interdependencies. Simple “autoregressive” models involve the dependence of variable \( x \) on the anterior value of the same variable, for instance, \( x_t = f(x_{t-1}) \), with any kind of relevant function.

Vector autoregressive (VAR) models are a generalization of such simple autoregressive models. Consider two stationary variables \( x_1 \) and \( x_2 \); each variable depends on its own past values but also on the present and past values of the other one. VAR models are very important in contemporary econometrics. They have been introduced by Christopher A. Sims (1980) as an alternative to macroeconometric models with a Keynesian flavor.

VEIL, IN AFRICAN AMERICAN CULTURE

The veil in African American culture is a mystical dimension of a spiritual belief system that traveled with slaves on the Middle Passage. An infant “born with a veil” of fetal membrane enveloping the head was interpreted as supernaturally gifted with a second sight, an ability to see into the future. Likewise, the seventh child of a seventh child would also be gifted with spiritual powers. The veil, also called a caul, like roots, charms, and conjurers, is a vivid aspect of African American spiritual, literary, and folklore tradition.

Moving beyond the mystical, African American sociologist W. E. B. Du Bois explored the notion of the veil from a societal perspective, using the metaphor of being “born with a veil” to describe black life in America, particularly the plight of the black American experience and the challenges facing African American culture. In his 1903 masterpiece The Souls of Black Folk, Du Bois articulates with poetic beauty and poignant accuracy the pain and confusion felt by an entire race of people as it sought self-understanding.

A sense of duality surrounds Du Bois’s veil metaphor: First is the physical delineation of blackness and whiteness, that semipermeable border that separates black and white cultures and forces blacks to learn to function in both worlds. Second is white people’s inability to view blacks as worthy Americans. Du Bois often felt despised by whites and was regularly asked, indirectly, “How does it feel to be a problem?” (1903, p. 1). This obstruction of vision is twofold, for the veil also refers to black people’s inability to see themselves beyond the prescient image projected onto them by whites. Realizing his racial identity, Du Bois states, “Then it dawned upon me with a certain suddenness that I was different from the others; … shut out from their world by a vast veil. I had thereafter no desire to tear down that veil, to creep through” (p. 2).

Faced with this problematic veil that separated the two worlds of black and white, blacks were forced to create a “twoness” or “double-consciousness.”

The Negro is a sort of seventh son, born with a veil, and gifted with second-sight in this American world—a world which yields him no true self-consciousness, but … this double-consciousness, this sense of always looking at one’s self through the eyes of others… One ever feels his twoness,— an American, a Negro; two souls, two thoughts, two unreconciled strivings; two warring ideals in one dark body. (p. 3)

But also drawing upon the positive spiritual qualities of the veil, Du Bois notes that a black person seeks “to merge his double self into a better and truer self” (p. 3).

A century later, Du Bois’s metaphor veil lives on in Behind the Veil: Documenting African American Life in the Jim Crow South, a comprehensive research project associated with the Center for Documentary Studies at Duke University. Historians conducted nearly 1,300 oral interviews with everyday men and women from the Jim Crow era, resulting in a book and audio documentary titled Remembering Jim Crow: African Americans Tell about Life in the Segregated South (2001). Much like the dualism of The Souls of Black Folk, Behind the Veil has its own dualism: to convey the oppression experienced by African Americans during Jim Crow but also their incredible hope and monumental efforts.

VEIL, IN MIDDLE EASTERN AND NORTH AFRICAN CULTURES

The veil—or hijab—is attire that is said to be women’s religious duty as well as a cultural requirement of personal modesty. Across the Muslim countries of the Middle East and North Africa, the veil takes varied forms: the headscarf, loose jacket, and long skirt ensemble seen in Egypt; the black cloak (chador) in Iran; the brightly-patterned silk scarf and long coat worn by Islamic women in Turkey; and the full niqab that covers the face and hands, which is worn by women affiliated with Islamist movements as well as many women in the Gulf countries. Not all Muslim women veil, and governments have taken different positions on veiling. For example, veiling in government agencies and universities is forbidden in Turkey and Tunisia but is compulsory in Iran and Saudi Arabia. Still, polemics surrounding hijab abound in every country, and scholars have written about the increasing observance of
the veil in the Middle Eastern and North African countries. Immigrant communities in Europe and North America also have seen veiling, leading to national debates and policy formulations. Commentaries and popular images depict the veil variously as symbolizing women's oppression or as a Muslim woman's cultural right.

During the era of early modernization and postcolonial nation-building, when national progress and the emancipation of women were considered synonymous, the veil was associated with national backwardness and with female illiteracy and subjugation. This viewpoint entailed discouragement of the veil and encouragement of schooling for girls. At certain times in Middle Eastern modern history the veil has been convenient to militants and political activists. In the Algerian war for independence against the French in the 1950s and the Iranian revolt against the shah in 1978, women used the veil to hide political leaflets and arms. But a paradox of the 1980s was that more and more educated women, including university students and working women, donned the veil. In Egypt, hijab included both modest dress and the more extreme niqab (Badran 1994).

Observers have raised a number of questions about veiling. Is veiling merely a matter of convenience and individual choice, or does social pressure play a part? If veiling is a “voluntary” identity marker of “The Muslim Woman,” what larger message does it send about women’s bodies and hair? What is the relationship between veiling/revealing, the growth of Islamist movements, and the policies of Islamist states? In the case of compulsory veiling, veiling is clearly tied to state policy and its patriarchal gender regime. But what of the expansion of veiling in Algeria, Egypt, Turkey, and among the Palestinians, where veiling is not mandated by the state?

One response has been to emphasize Muslim women’s “agency” in the decision to veil (El-Guindi 1981; Hoodfar 1991). In this view, veiling permits public roles for women from conservative families that would otherwise not allow “their women” access to higher education or employment. Hijab is a form of “protection” that allows the educated, professional woman to participate in public life and be both modern and Islamic. This viewpoint entails discouragement of the veil and encouragement of schooling for girls. At certain times in Middle Eastern modern history the veil has been convenient to militants and political activists. In the Algerian war for independence against the French in the 1950s and the Iranian revolt against the shah in 1978, women used the veil to hide political leaflets and arms. One response has been to emphasize Muslim women’s “agency” in the decision to veil (El-Guindi 1981; Hoodfar 1991). In this view, veiling permits public roles for women from conservative families that would otherwise not allow “their women” access to higher education or employment. Hijab is a form of “protection” that allows the educated, professional woman to participate in public life and be both modern and Islamic. There is also some evidence that voluntary veiling is not always an expression of affiliation with or support for an Islamist political movement; it could represent rejection of parental and patriarchal authority among rebellious young women. Some young women from nontraditional families who adhere to hijab aspire to personal autonomy and a more serious mien, especially at coeducational colleges.

Others have argued that the response of some women who are compelled to work for low wages has been an intensification of traditional modesty markers, such as veiling. Reluctantly working outside the home, and thus “exposed,” middle-class and low-income women must use every symbolic means at their disposal to signify that they continue to be “respectable” and worthy of protection. Arlene MacLeod (1991) called this “accommodating protest.”

The expansion of Islamist movements and the ideology of political Islam have led to increased veiling in at least three ways. First, Islamism places a high premium on sex segregation, a preference for the confinement of women to the private sphere of the family, male guardianship over women, and the veiling of women in public or before men who are not closely related—norms that Islamists in power have legislated. The wives, daughters, sisters, and other women supporters of Islamist movements all have been veiling. Second, the ideological exhortation that to be an authentic Muslim woman is to veil has created a political environment and cultural climate that have compelled many non-Islamist women to veil. The insistent message that veiling is a moral and religious requirement constitutes an effective ideological pressure. Third, in some instances Islamists have used intimidation and physical force against unveiled women—this has occurred in Algeria and among the Palestinians (Moghadam 2003).

Veiling reflects and encourages notions of women’s vulnerability, of their “difference,” and of the presumed dangers of the female body. Fatima Mernissi has pointed out that women’s bodies and their sexuality are regarded as potential sources of fitna (moral or social decay) and as such, veiling is meant to protect men, not women. In the same way that many feminists have decried the underdressing of women in Western contexts (Hollywood, the fashion industry, MTV, and so on) because of the way that this reduces a woman to her sexuality, so feminists regard the veil as reinforcing the idea of women’s bodies as sexual, dangerous, and a source of temptation (Mernissi 1987; Sabbah 1983).

Other scholars have noted that women’s bodies are the site of contestation over religious, national, and cultural identity (Kandiyoti 1991; Moghadam 1994). Islamists in Algeria, Iran, Jordan, Palestine, and elsewhere have exhorted women to veil, to have more children, and to steer clear of “alien” ideologies. Women who do otherwise are branded as cultural traitors, morally repugnant, and religiously damned. The concept of gharbzadegi—widely used in postrevolutionary Iran and variously translated as “Westoxication” or “Westitis”—illustrates this point. Through those members who are “struck by the West,” notably women, imperialism can penetrate the society and wreak havoc on the culture. The claim was made that by depriving women of chastity, modesty, and honor through notions of autonomy, sex appeal, and so on, colonialists and imperialists had been able to weaken...
Muslim cultures. This is said to have happened in Algeria under French colonialism and in Iran during the rule of the pro-American shah. It follows that the main antidote to the virus of gharbzadegi is the veil. Furthermore, veiling must be compulsory in order to protect the cultural identity and integrity of the group and of its female members (Najmabadi 1991; Tohidi 1994). A similar exhortation was made by the Ikhwān Muslemin (Muslim Brothers) of Jordan: “How can God’s victory prevail when women adorn themselves openly and mix with men, and when defiance of God’s law continues day and night? The enemy relies on you, my sister, to strike at this nation from within, as if the stabs we receive from the outside were not enough” (Taraki 1995, p. 660).

Faegheh Shirazi (2001) notes that veiling is heavy with meaning; it has been a symbol of cultural identity, religious assertion, gender oppression, and sexual mystery. The “fetishism of the veil” is found among Westerners and Islamists alike. She argues that while the veil has “semantic versatility” it often serves political agendas. In Iranian politics, and especially during the war with Iraq in the 1980s, the connection between hijab and jihad was maintained through the strategic use of postage stamps, posters, banners, billboards, and other print material depicting veiled women as strong supporters of the war. She also describes the preoccupation with bad-hijabi (malveiling) on the part of the Islamic authorities in Iran.

In its most innocuous form, veiling is a sign of piety and a form of protection against the male gaze. Increasingly, it is the line of demarcation between the Islamist/Islamic community and non-Muslim communities, a shield against the slings and arrows of imperialists, and protection against the dangers of female sexuality. Veiling can symbolize the imposition of identity and “morality.” In the Islamic Republic of Iran, even non-Muslim citizens—Christian, Jewish, and Zoroastrian women—have been forced to veil in public. Whether compulsory or “encouraged,” veiling has been a mechanism of social control: the regulation of women.

VENTURE CAPITAL

Venture capital (VC) is capital used by private equity funds to support the creation and growth of businesses; it is characterized by a tradeoff between high risk and high rates of return. Most VC has been invested in technology-
oriented companies and projects. Because it is independent and professionally managed, VC is a crucial equity type of external financing for privately held companies that seek to grow rapidly. As a result, VC investments play a critical role in economic development.

Newly created firms that are expected to grow quickly into big companies often do not have sufficient funds to finance their projects and thus need outside financing. These firms are subject to potential capital constraints; that is, they have difficulty receiving bank loans and other types of standard financing because of a limited track record and uncertain future prospects. VC is a professionally managed pool of money raised for the specific purpose of making equity investments in such companies. In addition to providing new capital during critical stages of development, professional management adds value to expansion through screening, monitoring, and aiding in decision-making. A typical VC firm receives many proposals per year, but only approves a very small percentage.

The first formal private equity fund was formed in 1946 in Boston to provide financing to several companies that had developed new technologies during World War II (1939–1945). The first VC limited partnership was formed in 1958. Even though several other VC companies were established later on, the total average annual VC investment did not exceed a few hundred million dollars until the end of the 1970s. During the 1980s, VC firms provided capital to the most successful high-technology companies, such as Cisco Systems and Microsoft. Since then, the private equity industry has been experiencing tremendous growth in the United States, both in terms of the amount of capital invested and in terms of returns. VC market growth also spread abroad, first to the U.K. and then to continental Europe and beyond. Differences in the nature of financial markets from country to country are the main reasons for the varying maturity of VC markets. For instance, there is a clear institutional separation between investment banks and the VC industry in the United States, but in countries with relatively young financial markets, the functions of VC firms are often performed by major investment banks as well as private equity partners. Whereas VC firms provide funds to firms at early stages of their development in the United States, in Europe and in developing countries VC companies prefer firms that have already developed and started marketing their products.

The supply of VC is determined by investors’ willingness to provide funds to venture firms. This willingness depends on the expected rate of return on investments. High-tech companies with the potential to grow rapidly are also highly risky investments. VC firms that become major equity owners in such new firms are only willing to finance high-reward investment proposals because they also have responsibilities to several other funding sources, such as individual investors, investment bankers, subsidiaries of banks, and other corporations. In order to make money on their investments, a VC fund needs to turn the illiquid stakes in private companies into realized return, for example by taking a company public. The most profitable exit opportunity for VC firms is an initial public offering (IPO). In an IPO, the VC fund assists the company in issuing shares to the public for the first time. The exit is an important aspect of the VC business because investors in a VC need a way to evaluate the performance of VC funds in order to decide whether to provide further capital. On the stock exchange, the success of existing strategy is demonstrated by lower underpricing (the difference between offer price and first-day trading price) and by high long-term performance (measured against certain benchmark investments). Empirical research shows that VC backing reduces the degree of IPO underpricing, and that the long-term stock returns (up to five years) of companies backed by VC funds are substantially better than those of companies without VC.

VERBA, SIDNEY

1932–

Sidney Verba is Carl H. Pfporzheimer University Professor of Government at Harvard University and was director of the University Library from 1984 to 2007. Professor Verba has held many important positions in the discipline of political science, including chairman of the American Political Science Association and coordinator of national research committees. Verba is also a fellow of a number of
academies and learned societies and has received numerous prizes, including the 2002 Johan Skytte Prize in Political Science at Uppsala University in Sweden.

Verba is one of the leading scholars in the field of political behavior. Since the mid-twentieth century, this branch has become so internalized in the way political scientists conduct their research that they no longer think of it as a special subdiscipline. Verba's textbook, *Designing Social Inquiry* (1994), authored with Gary King and Robert Keohane, beautifully summarizes how research problems in political science should be formulated, how variables are identified, how data is collected, and how hypotheses are tested and conclusions drawn.

Verba's contribution to political science is basically of a substantive nature. In one of his most famous books, the prize-winning *Participation in America* (1972), written with Norman H. Nie, Verba stresses that participation constitutes the very core of democracy—the more participation, the more democracy. Participation widens citizens' horizons and teaches them responsibility for others. Participation has consequences—for power and influence and for what issues are pursued and decided upon. However, participation is not equally distributed between social groups. Socioeconomic status is the best explanation for the variation in participation—the SES (socioeconomic status) model. There is a conflict between participation and representation. When new channels are opened up for political participation, those citizens who have time and money increase their influence further. The well-to-do are thus overrepresented in political parties and organizations, and they are especially among the most active in the Republican Party. But there are also countervailing powers. Verba underscores the political consciousness of black citizens, which he saw in the 1970s as an important political potential.

The level of political inequality also varies between countries. It is especially striking in the United States, whereas the correlation between social status and participation is much less marked in such countries as Great Britain, Italy, Mexico, and Germany. These nations were included in Verba's *The Civic Culture* (1963), a book that took a pathbreaking classificatory approach to the comparative study of political systems, published by Verba in cooperation with political scientist Gabriel Almond (1911–2002). In Europe, the political mobilization of the underprivileged by the labor movement has leveled out but not obliterated differences in participation; the SES model is still valid.

**VERDOORN’S LAW**

Productivity growth is the key to economic development. The continuous increase in labor productivity, defined either as the output per worker or the output per hour worked, is what allows human societies to experience a rise in their per capita income even in face of a growing population. Productivity growth is usually associated with technological innovations, but since the beginning of the Industrial Revolution in the eighteenth century, it became clear to social scientists that economic growth itself may foster productivity growth through the division of labor, as pointed out by Adam Smith in 1776. However, despite the direct evidence that productivity rises with the level of output in manufacturing, the concept of increasing returns was ignored through most of the nineteenth century in the mainstream economic literature because the hypotheses of decreasing marginal returns to capital and
labor and constant returns to the scale of production became preponderant in neoclassical economic theory.

The importance of increasing returns for economic growth was revitalized only in the early twentieth century by Allyn A. Young (1928), who emphasized not only the reduction in the average cost of production brought by output growth in manufacturing but also the product diversification that characterizes an increase in the division of labor. Verdoorn’s law, an attempt to quantify this relationship, is named after the Dutch economist P. J. Verdoorn, who published a paper in 1949 in which he measured the impact of economic growth on labor-productivity growth in manufacturing for a group of countries in the late nineteenth century and early twentieth century.

In general terms, Verdoorn’s law implies the existence of a stable and positive causal relationship from the growth rate of output to the growth rate of productivity in manufacturing in the long run. More formally, let \( p \) and \( q \) represent the growth rates of labor productivity and output in manufacturing, measured in logarithmic terms. Verdoorn’s law was originally estimated as \( p = a + bq \), where \( b \) is a positive parameter that measures the elasticity of labor productivity to output. The estimate of \( b \), known as the “Verdoorn coefficient,” in most empirical studies takes a value around 0.5. The intuitive meaning of this result is that an additional one percentage point increase in the growth rate of output leads to a half percentage point increase in productivity in manufacturing. Since \( p = q - n \), where \( n \) is the growth rate of employment in manufacturing, Verdoorn’s law can also be estimated as \( n = -a + (1 - b)q \).

The theoretical foundation of Verdoorn’s law is the existence of economies of scale in manufacturing, that is, the fact that the average cost of production falls with an increase in the amount of goods produced. The sources of economies of scale within a firm or industry are usually divided into two categories: static or dynamic. Static economies of scale come from the fact that most processes of production incur a fixed cost, that is, a cost that has to be paid no matter whether anything is produced. As a result, the higher the level of production, the lower the average fixed cost per unit produced and consequently the higher the economy of scale. It should be noted that static economies of scale are reversible because, if production is reduced, the average fixed cost rises. Dynamic economies of scale come from the productivity gains associated with innovations brought about by the increase in production. The intuition here is that the dynamic economies arise from learning by doing and as such are irreversible. Even if the level of production falls, the new knowledge acquired from experience does not vanish.

Verdoorn’s (1949) study of productivity growth was published in Italian and went unnoticed by the majority of the economic profession until Nicholas Kaldor (1966) drew attention to it. As summarized by Anthony P. Thirlwall (1983), Kaldor proposed that three growth laws characterized economic development: (1) the higher the growth rate of output in manufacturing, the higher the growth rate of gross domestic product (GDP); (2) the higher the growth rate of output in manufacturing, the higher the growth rate of labor productivity in manufacturing, as proposed by Verdoorn; and (3) the higher the growth rate of output in manufacturing, the higher the growth rate of labor productivity outside manufacturing.

In its broadest sense, Verdoorn’s law implies the possibility of endogenous or induced technical change, which forms the basis of theories of economic growth based on increasing returns. In neoclassical theories economic growth is usually explained from the supply side, and Verdoorn’s law tends to appear as a learning function that links the growth rate of labor or multifactor productivity to the growth rate of the stock of human and physical capital. In nonmainstream theories of Keynesian inspiration, economic growth is usually determined from the demand side, and therefore Verdoorn’s law tends to appear as the explanation of how demand problems can result in uneven development, that is, in permanent growth divergences across countries or regions.

The logic of demand-driven growth divergences is clear and intuitive. If productivity growth is a positive function of economic growth, then an initial increase in aggregate demand can set off a cumulative process along the lines proposed by Gunnar Myrdal (1957), in which productivity gains increase profits and wages, which in its turn leads to another round of demand expansion and so on. The main economic implication of Verdoorn’s law is therefore that growth may be self-reinforcing, especially if we bring international trade into the analysis. The basic idea here is that fast-growing economies may be able to maintain their international competitiveness because of the fast productivity growth induced by income growth itself. By analogy, slow-growing economies may not be able to break out from their situation because of the slow productivity growth induced by their very own poor growth performance.

Since its revitalization by Kaldor, Verdoorn’s law has been the object of many studies, and the empirical debate tends to revolve around four main issues. First, if productivity growth is exogenous across regions, Verdoorn’s law may be spurious because it may be productivity that drives output instead of the other way around. The solution for this possible reverse causation is to investigate whether Verdoorn’s law holds across regions that share the same
technology. Second, it may also be the case that productivity growth depends on the level of capital per worker, so that Verdoorn's law finds an influence of output growth on productivity growth because the former functions as a proxy of capital growth. The solution for this problem is to include the capital per worker as a separate explaining variable when estimating Verdoorn's law. Third, Verdoorn's law may actually be a misspecified labor demand function, that is, a demand function that ignores the impact of the real wage in the determination of employment. The obvious solution for this problem is to include the real wage as a separate explaining variable when estimating Verdoorn's law. Finally, because firms do not adjust employment as fast as output in the face of demand fluctuations, productivity tends to increase during upswings and fall during downswings because of labor hoarding. If that is the case, Verdoorn's law may actually be just a short-run phenomenon resulting from business fluctuations, known as Okun's law in economics. The natural solution to this problem is to control for changes in the business cycle when estimating Verdoorn's law.

As usually happens in economics, after decades of empirical studies there is evidence both in favor of and against Verdoorn's law. From the many studies on North America and Europe surveyed by John McCombie, Maurizio Pugno, and Bruno Soro (2002), the balance seems to confirm Verdoorn's law. When we consider developing economies, Vaishali Mamgain (1999) finds evidence in favor of Verdoorn's law only in one of six newly industrializing countries of East Asia, whereas Thirlwall and Heather Wells (2003) find evidence in support of Verdoorn's law for a sample of forty-five African countries. In Latin America, E. Luis Lemos Marinho, Cláudio André Gondim Nogueira, and Antonio Lisboa Teles da Rosa (2002) find mixed evidence for Brazil. It will probably take some time until the increasing number of applied studies on developing economies tend one way or another.

**VESEY, DENMARK**

c. 1767–1822

The man later known as Denmark Vesey was born around 1767, probably on the Caribbean island of Saint Thomas. Joseph Vesey, a Carolina-based slaver, purchased the boy in 1781 as part of a cargo of 390 bondpeople. During the passage to the French colony of Saint-Domingue (Haiti), Vesey noticed the child’s “beauty, alertness, and intelligence” and employed him as a cabin boy. But when the ship reached Cap François, the captain “had no use for the boy” and turned him over to his colonial agents. Either traumatized by his new life in Saint-Domingue or feigning illness, the child began to display “epileptic fits.” Returned to the docks, a physician “certified that the lad” was unwell, which cancelled the sale. When Joseph Vesey returned to Cap François on April 23, 1782, with a new cargo of Gold Coast slaves, he was forced to take the child back. The fits promptly ceased, and Vesey decided to keep him as a servant.

Charleston authorities later described the child as a person of “superior power of mind & the more dangerous for it.” The captain saw only the value of a tall, muscular boy already conversant in two languages. Vesey gave the boy a new name, Telemaque, after the son of Homer’s Odysseus; over time, Carolina bondmen either punned or
corrupted the name into Denmak, and then finally Denmark.

In the spring of 1783, following the British evacuation of South Carolina, Joseph Vesey settled into Charleston as a ship charger. At some point during this period, Denmark married an enslaved woman named Beck. Beck had several masters over the course of her life, but she remained married to Denmark long enough to give birth to at least three of his children. Two of his sons were named Polydore and Robert; a third, Sandy, would be the only child to be implicated in his 1822 plot. Toward the end of his life, Denmark Vesey married again. His last wife, Susan, was born a slave around 1795. She was the only woman to carry his surname. Some historians have speculated that Vesey practiced polygamy, although no evidence exists to support the theory.

On September 30, 1799, Denmark happened upon a handbill announcing the “East-Bay Lottery,” and bought a ticket. In November, Charleston newspapers declared his ticket the winner. The prize was $1,500, a princely sum that slaves who hired their time would take ten years to acquire. Joseph Vesey agreed to sell Denmark his freedom for $600; the contract was signed on December 31, 1799. After seventeen years as a Charleston slave, the thirty-three-year-old Denmark was free.

Chained to the South by family ties, Denmark remained in the city and apprenticed himself to a carpenter, an easy trade to learn and a lucrative business as Charleston expanded up the peninsula. At the same time, he adopted Vesey as a surname, probably as a linguistic tie to an established businessman whose name could help to secure clients. Vesey threw his enormous energies into his business, and according to one former slave, Denmark labored “every day at the trade of carpenter” and “soon became much respected and esteemed by de white folks.” But because of competition from white carpenters, free mulattoes (whose fathers provided business contacts), and enslaved craftsmen (who lived with their masters and paid no rent), Vesey barely maintained a modest income. Despite published claims made in 1822 that he died a rich man worth nearly $8,000, there is no evidence that Vesey ever owned a single piece of property.

Around 1818 Vesey joined the city’s new African Methodist Episcopal congregation, the center of Charleston’s enslaved community. Sandy Vesey also joined, as did four of Vesey’s closest friends: Peter Poyas, a literate ship carpenter; Monday Gell, an African-born Ibo who labored as a harness maker; Rolla Bennett, the manservant of Governor Thomas Bennett; and “Gullah” Jack Pritchard, an East African priest and woodworker purchased in Zinguebar in 1806. The temporary closure of the church by city authorities in June 1818 and the arrest of 140 congregants, one of them presumably Vesey, reinforced the determination of black Carolinians to maintain a place of independent worship and established the motivation for Vesey’s conspiracy. In 1820 several “Negroes was taken up” for holding a late-night service at the church, and city authorities warned that they would not tolerate class leaders conducting instructional “schools for slaves,” as “the education of such persons was forbidden by law.” The “African Church was the people,” Gell replied. He and Pritchard had considered insurrection in 1818, “and now they had begun again to try it.”

At the age of fifty-one, Vesey briefly thought about emigrating to the English colony of Sierra Leone. But as Beck’s children remained slaves, Vesey resolved instead to orchestrate a rebellion, followed by a mass exodus from Charleston to Haiti. President Jean-Pierre Boyer had recently encouraged black Americans to bring their skills and capital to his beleaguered republic. Vesey did not intend to carry in Charleston long enough for white military power to present an effective counterassault. “As soon as they could get the money from the Banks, and the goods from the stores,” Rolla insisted, “they should hoist sail” for Saint-Domingue and live as free men.

Vesey planned the escape for nearly four years. His chief lieutenants included Poyas, Gell, Rolla Bennett, and “Gullah” Jack Pritchard. Although there are no reliable figures for the number of recruits, Charleston alone was home to 12,652 slaves. Pritchard, probably with some exaggeration, boasted that he had 6,600 recruits on the plantations across the Cooper and Ashley rivers. The plan called for Vesey’s followers to rise at midnight on Sunday, July 14—Bastille Day—slay their masters, and sail for Haiti and freedom. As one southern editor later conceded: “The plot seems to have been well devised, and its operation was extensive.”

The plot unraveled in June 1822 when two slaves revealed the plan to their owners. Mayor James Hamilton called up the city militia and convened a special court to try the captured insurgents. Vesey was captured at Beck’s home on June 21 and hanged on July 2, together with Rolla, Poyas, and three other rebels. In all, thirty-five slaves were executed. Forty-two others, including Sandy Vesey, were sold outside the United States; some, if not all, became slaves in Spanish Cuba. Robert Vesey lived to rebuild the African Church in the fall of 1865.

VETO

The veto is the power to block or reject a proposed decision. In Latin, the word veto literally means “I forbid.” The veto is generally an executive prerogative, as in the power of a chief executive to reject a bill or resolution that is proposed by the legislature. This power may also extend to an official authority or body, such as an international organization (e.g., the United Nations). While executive veto power is often discussed in conjunction with the authority granted to governors or presidents in the United States, it is a hallmark of a variety of separation-of-powers systems in other countries. The veto provides an important check on the power of the legislature in the lawmaking process.

In the United States, veto power is given to the chief executive by the U.S. Constitution. Even though this executive power has existed since America’s founding, its use was often construed narrowly. Prior to the administration of President Andrew Jackson (1829–1837), the veto was not used by presidents to object to legislation that was viewed as questionable on policy grounds. Rather, legitimate use of the executive veto involved objecting to legislation that was either poorly drafted or clearly unconstitutional. Following Jackson’s presidency, however, this practice changed, and modern U.S. presidents routinely veto legislation to which they object for political reasons. In contemporary American politics, the incidence of presidential vetoes is almost always greater under divided government, where the executive is controlled by one political party and (at least one chamber of) the legislature by the other.

Although vetoes occur relatively rarely in the legislative process, scholars are drawn to study them because vetoes carry clear policy implications. Indeed, the use of the veto by an executive is an ideal example of negative agenda control. The veto creates an opportunity to block legislative action, but it does not give the executive the power to alter proposed legislation after the fact. Nonetheless, Charles Cameron (2000) asserts that chief executives regularly engage in bargaining with legislators in an attempt to shape legislative outcomes at various stages of the process. In many respects, a credible veto threat may be sufficient to force compliance on the part of reluctant legislators who would prefer not to prolong a legislative battle over a controversial bill or resolution. To avoid “losing” to the president, one or both chambers of the legislature may be willing to make concessions if the price of passage necessitates it.

Although veto power is usually associated with the executive office, legislatures may hold veto power as well. In a bicameral legislature where both chambers must pass legislation in identical form before it is sent to the executive for approval, for instance, either chamber can block legislation, which is the equivalent of a veto. Moreover, a veto does not always require action on the part of an executive to effectively block legislation. If the U.S. Congress sends a bill to the president and adjourns prior to the ten days given to the president to sign or veto the measure, the bill essentially dies through what is known as a pocket veto. Conversely, the measure will automatically become law without the president’s signature if Congress remains in session past the ten-day limit. Thus, inaction on the part of the executive still can have tangible legislative consequences, contingent on the behavior of the legislature.

Veto power is by no means absolute. Consistent with the notion of both shared and separated powers, the legislature is typically given the opportunity to override an executive veto if members can garner the necessary votes. The override authority granted to legislatures provides an opportunity for offsetting an executive veto in an attempt to alter policy outcomes. In many cases, a legislative override requires a supermajority. In the U.S. Congress, for instance, two-thirds of both chambers must successfully vote to override an executive veto. While most override attempts fail as a result of the supermajority requirement, David Rohde and Dennis Simon (1985) maintain that the uncertainty associated with a potentially successful override provides an important check on unilateral power on the part of the executive.

VIDEO GAMES

The very mention of video games conjures a myriad of different thoughts, emotions, and concerns. Originally, video games were released for the Atari gaming system in 1973, and for the Apple 2e (1984) and Apple 2gs (1986). Coin-operated gaming machines surfaced in shopping malls and in various stores during the late 1970s and early 1980s. Nintendo debuted video games as early as 1976. Although games have appeared on computer systems in the past and continue to flourish today, the two major gaming systems that paved the way for today's famous systems were the original Sega and the Nintendo gaming system. Nintendo is the oldest of the game systems companies and is currently the leader in handheld console sales. Sega offered the GameGear handheld during the 1990s. Nintendo's first offering had been Game Boy, and as of 2007 the graphically intense DS was for sale at retail outlets. The original Nintendo saw games in production from 1983 to 1994. Super Nintendo remained in production from 1990 to 2000, Nintendo 64 from 1996 to 2002, and GameCube from 2001 to 2007.

The games released may seem primitive relative to those on the market in 2007, but for the players they represented something prodigious. Games such as Pac-Man, Galaga, Pong, Budokan, Ultima, Might and Magic, Zillion, Rocky, The Adventures of Zelda, Donkey Kong, and the cult favorite, Super Mario Brothers, have entertained and delighted millions around the world. Donkey Kong was released exclusively for the Nintendo system in 1981, and the prototype for future Super Mario Brothers games appeared on the market in 1983. The Legend of Zelda became another instant classic after its arrival in early 1986.

The cult favorite game Mike Tyson's Punch-Out arrived to much fanfare in 1987. Even family restaurants welcomed the coin-machine version of the game into their establishments. The very mention of Mike Tyson in association with a video game proved to be a brilliant advertising mechanism. Meanwhile, Nintendo's Super Mario Brothers games, a smash hit when they arrived in 1985, have been criticized because they contain violent images. The objective is to slay the evil serpentine “end-guys” at the end of each level and jump on the mushroom men. To achieve this goal a player searches for special character upgrades such as the chance to wield fireballs, to be able to fly, and the like. Meanwhile, Nintendo’s competitor Sega flooded the market with games as early as 1981. Developed originally as a prototype for U.S. servicemen stationed overseas, it too achieved popularity. Although many of the games offered for the Sega system did not receive as much acclaim as those invented by Nintendo, many gamers have heralded its superior game play and controllers. Sega’s smash video game hits included Rocky (1987), Zillion (1987), Phantasy Star II (1989), and the ultimate game of strategy and surprise, Herzog Zwei (1990).

Nintendo’s second smash hit system, Super Nintendo, was even more successful. Super Nintendo offered Super Mario Land, an adaptation and graphically superior version of its prototype. Recently, Nintendo has capitalized on the success of these games by introducing Super Mario Brothers for their handheld system, the Nintendo DS. Additionally, Nintendo’s third hit system, the Nintendo 64, offered a variety of Mario Brothers games in 3-D.

The inundation of the market with video consoles has not come without scrutiny from various sectors of society. One area of concern is that young males favor video game play more than females do. Critics and watchdog groups believe this leads to aggression and violent impulses in men. As early as the late 1980s studies showed that male characters vastly outnumbered female protagonists or heroines. Conversely, scholars have recently argued that those who grew up playing video games may actually fare better in the workplace, having gained valuable knowledge and insight into cognitive behavior and how to socialize with coworkers. As technology has advanced, so have the messages propounded in the games themselves. With the ability to command ostensibly real-life armies and to dictate bombing campaigns and infantry showdowns, skilled game players may act as mock generals. Although this may lead to an artificially enhanced sense of self-power, it can also serve as a lesson about the viciousness of warfare, the consequences of failure, and the large number of casualties experienced during a heated battle. Sports games such as NBA Live, Madden NFL, Smackdown! vs. RAW, and NHL are interactive and promote athletes as supermen and role models, and game players often aspire to become professional entertainers as a result.

As early as 2000, video games had finally become mainstreamed in society. Teenage boys are not the only group interested in acquiring and playing the big three: Microsoft’s Xbox 360, Sony’s PlayStation 3, or Nintendo’s newest console, the Wii. The competition is on for these companies to produce high-definition-ready systems and games to correspond with this capability. Regardless, the popularity of these systems has been a cause for concern for social and civil rights groups. The most infamous game...
in the market has continued to be the series Grand Theft Auto, a lucrative series developed by Rockstar Games. A player may purchase prostitutes, destroy private property, wreck other people’s automobiles, and essentially wreak havoc on the streets of a major city. This has captured the attention of city councils, Congress, and any number of outraged advocacy groups. As portrayed in the game, mimicking and glorifying gang behavior is disruptive and dangerous. Two staff writers for the Washington Post, Eric M. Weiss and Jose Antonio Vargas, have pointed out that these games are often sold or rented to children (2005). Although the revenue for game sales may be extraordinary, the social consequences are regarded by some as dire. Psychologist Craig Anderson has published findings asserting that adolescents playing violent video games experience accelerated heart rates and adrenaline rushes that may translate into violent behavior in real life.

Many of the most educational games are offered as PC games and are frequently priced lower than those created exclusively for one of the big three systems. Games such as Battle Chess or Chessmaster offer tutorials in how to improve one’s chess skills. Colonization and Civilization are examples of intellectually stimulating games that have been offered in the past. Players of these games learn about world history, world leaders, inventions, architecture, the development of civilizations, and how to defeat an opponent by exercising the mind.

Clearly, video games raise awareness of the level of violence and crude sexuality that exist in contemporary society. However, it must not be ignored that these games serve several important purposes. Video games display images that brighten the imaginations of children, many are educational, and the old cliché about hand and eye coordination being sharpened through repeated game play is scientifically valid. When examining and engaging in discourse about societal problems, video games deserve to be discussed in a balanced manner and with the full spectrum of perspectives in order to recognize their positive impact on society as a whole.

VIETNAM WAR
The Vietnam War has been permanently singed into the American consciousness, and its impact will be felt for years to come in foreign policy debates. The conflict produced four million killed or wounded Vietnamese—one-tenth of the combined population of North and South Vietnam at the onset of the war—and ranks as the United States’ longest and costliest overseas conflict, with the loss of 57,939 American lives and $150 billion in U.S. military spending. Moreover, Vietnam was a critical issue in the foreign policy of six successive U.S. presidential administrations.

BACKGROUND
A thorough understanding of the Vietnam War must begin with the end of World War II (1939–1945) and the onset of the cold war. To be sure, Communist Vietnam and the United States had interacted before 1946, notably when Ho Chi Minh requested Vietnamese self-determination at the 1918 Versailles Peace Conference ending World War I (1914–1918) and when he made his 1945 independence speech, which quoted the U.S. Declaration of Independence as a band played the “Star Spangled Banner.” But it was the specter of a strengthened Soviet Union threatening Asia that spurred U.S. involvement in Indochina, the French colonial holdings that comprised present-day Vietnam, Cambodia, and Laos. In 1945 France had petitioned for the return of Indochina, which it had surrendered to the Japanese earlier in World War II. A year earlier, U.S. president Franklin Roosevelt, a fervent anticolonialist, had written to the British ambassador that he believed “Indochina should not go back to the French,
but that it should be administered by international trusteeship.“

But by the summer of 1950, four years into the French Indochina War, Roosevelt was long dead, Harry Truman had assumed office, and the geopolitical landscape looked remarkably different: the Soviet Union had detonated an atomic bomb, Chinese communists had completed their conquest of the mainland, Senator Joseph McCarthy had initiated his now infamous campaign against “softness” toward communism, and the United States was involved in a full-scale war against a Soviet satellite in Korea. In such a political climate the United States regarded Ho Chi Minh and his organization the Viet Minh (the abbreviation for the Vietnam Independence League, formed in 1941) as part of a wider communist threat. The image of France in U.S. policy circles also had evolved with the changing times; the country was no longer a nation of greedy imperialists, but a stalwart opponent of the spread of the “red menace” in Asia. Thus, in much the same spirit as the Berlin airlift (1948–1949) and the postwar provision of monetary assistance to Greece and Turkey, the United States offered financial support to France in its quest for repossession of Vietnam. The allotment in 1950 started at $10 million, but it rapidly grew to $1.06 billion by 1954. In fact, a full 80 percent of the French war effort was paid for by the United States.

Despite the substantial U.S. support, the French were unable to prevail, and they eventually withdrew entirely after the battle of Dien Bien Phu in spring 1954. The resounding defeat (13,200 of the 16,000 French soldiers were either killed or captured) drove both sides to the bargaining table (along with, among others, the United States, China, and Soviet Union) at the 1954 Geneva Conference, where an agreement was reached to temporarily partition the country at the seventeenth parallel. A demilitarized zone (DMZ) now divided two governments: the communist North (the Democratic Republic of Vietnam) led by the Viet Minh, and the anticommunist South (the Republic of Vietnam) under the emperor Bao Dai.

The seeds of war were sown in the very language of the Geneva Accords, which called for an election to take place in July 1956 to choose the government of a reunified Vietnam. There was considerable consternation that a Communist government could prevail in a democratic election: Ho Chi Minh had become a popular revolutionary figure throughout Vietnam and, more importantly, no southern leaders had emerged with the charisma to best him in an election. Certainly, few Vietnamese would be willing to support an emperor who owed his very position to French colonialism. A Communist win would pose a setback to Eisenhower’s global strategy of “rolling back” the Communist threat, and U.S. officials warned that the loss of Vietnam would cause a chain reaction, much like the falling of dominoes, as other Southeast Asian nations succumbed to Communist pressures. Recent scholarship has refuted this “domino theory” by arguing that the United States’ military advantage over the Soviet Union at that time demonstrates that important U.S. policymakers such as Secretary of State John Foster Dulles were less afraid of funding off Communist insurgencies and more interested in projecting U.S. power in the region.

Eventually the United States chose to throw its support behind Ngo Dinh Diem, the prime minister of South Vietnam, who was nominated in 1954 by Emperor Bao Dai in the midst of the Geneva Conference. Although he possessed staunch anticommunist credentials, Diem was handicapped by his Catholicism (a religion shared by only 15% of the country’s population), his residence in the United States during the war against the French (which prevented him from capitalizing on the nationalist fervor), and his lack of many political allies other than his own powerful family. He needed help to build a political base and popular support before he could possibly succeed in an election. The United States was willing to offer that assistance, in part because of Diem’s cultivation of important political figures such as intelligence officer Colonel Edward G. Lansdale, and it began channeling aid through Diem, informing all potential rivals that future assistance hinged on Diem’s position at the helm. The gamble to support Diem until he could consolidate power and institute democratic reforms was the means by which the United States found itself inextricably linked to the southern regime.

**THE POLICE ACTION**

The issue of which side first violated the Geneva Accords will forever remain the fault line dividing historians of the war. Did South Vietnam violate the accords by postponing the elections, claiming (with U.S. support) that free and fair elections could never take place under a Communist government? Or did North Vietnam violate the terms of the accords through its military assistance to Communist guerrillas in the South, the National Liberation Front (NLF)? Although some have claimed that the NLF (also called the Vietcong) was always composed of northern agents and controlled by Hanoi, and not an indigenous popular movement of the South, there was no clear political relationship between the northern government and the growing insurgency in the South until northern leaders decided in May 1959 that they needed to take control of the movement.

Whatever the answer, the South found itself embroiled in a deadly conflict with the NLF, which had entrenched itself in the Mekong Delta as early as 1957 and in the central highlands by 1958. Afraid that Diem’s
power might be threatened by the conflict, the United States almost immediately lent him military assistance. The first deaths recorded on the U.S. Vietnam War Memorial are from 1957, but for the most part the U.S. military’s role remained minor until May 1959, when U.S. military advisors were placed with South Vietnamese regiments as part of a police action. Although the United States described this move as aiding an anti-Communist ally, North Vietnam interpreted the assistance as a continuation of the Western colonialism begun by the French.

The U.S. commitment to Vietnam expanded under the Kennedy administration at the end of 1961 after a series of incidents (most notably the Bay of Pigs) allowed the Republican opposition to portray him as soft on Communism. Consequently, Kennedy chose to take a hard line against the advance of Communism in Southeast Asia, expanding the number of military advisers from 900 to 3,200 by the end of 1961 and then to 11,300 by the end of 1962. Despite these large increases in advisers and despite optimistic Defense Department reports to the contrary, little progress was being made in quelling the insurgency. Prominent U.S. officials began to blame this failure on Diem, claiming that rampant corruption by his friends and family, lack of progress on land reform, and, above all else, an anti-Buddhist policy, were causing him to lose favor with Vietnamese citizens. Diem’s relationship with Buddhists was highlighted by a May 1963 incident in Hue when a deputy provincial chief gave orders to fire on 20,000 Buddhists at a religious celebration. Nine people were killed, and the Buddhist monk Quang Duc was prompted to burn himself a month later, calling for Diem to “show charity and compassion to all religions.” Photographs of his self-immolation appeared in U.S. newspapers and were thought to undermine support for the war effort. Small-scale opposition to the war, mainly on U.S. college campuses, erupted not long after the incident.

Putting pressure on Diem, the United States called for South Vietnamese military leaders to act against Diem’s excesses. How much the United States knew of the southern military’s true plans is a matter of intense debate, but on November 2, 1963, Diem was overthrown in a coup and executed, and General Duong Van Minh (or Big Minh) came to power. (Minh lasted less than two months before another military coup installed Nguyen Khanh.) The overthrow of Diem was followed by an announcement on November 15 that the United States would begin withdrawing 1,000 troops. The withdrawal never happened because a week later Kennedy was assassinated and Vice President Lyndon Johnson assumed the presidency. More optimistic about the potential for U.S. victory, Johnson increased the number of U.S. advisers to 21,000.

**THE ONSET OF WAR**

The Gulf of Tonkin incident served as the catalyst to full U.S. military involvement in Vietnam. On August 2, 1964 the USS Maddox was conducting a routine reconnaissance mission in the gulf when it was fired on by North Vietnamese coastal defense forces. The Maddox easily repelled the attack with air support from the nearby USS Ticonderoga, destroying one torpedo boat in the encounter. President Johnson, who was mired in a tough election campaign, chose a firm but restrained response, rejecting reprisals against the North but warning Hanoi that “grave consequences” would result from further unprovoked military attacks. Then, on August 4, the Maddox and USS Turner Joy picked up radar signals of an apparent torpedo attack from North Vietnamese vessels, and for two hours the ships responded with a torrent of fire against radar targets and took a series of evasive actions. Johnson ordered retaliatory air strikes on North Vietnamese targets and used the event to persuade Congress to pass the August 7 Gulf of Tonkin resolution that authorized the president “to take all necessary steps, including the use of armed force.”

Recent scholarship has examined whether the North Vietnamese ever actually attacked during the Tonkin incident. Maddox captain John J. Herrick conceded that the radar signal may have been nothing more than an “overeager sonar man” who “was hearing the ship’s own propeller beat.” The National Security Agency admitted to translation errors in intercepted Vietnamese transmissions that were used as grounds for the second attack. Senator William Fulbright confessed that he felt hoodwinked by the information presented in the 40-minute Senate debate. Most importantly, the scholar Gareth Porter in *Perils of Dominance* (2005) claimed that important information that cast doubt on the attack may have been concealed from Lyndon Johnson by Robert McNamara, his own secretary of defense.

Thus began the Vietnam War. The United States convinced Australia and New Zealand to contribute troops and material support, and in March 1965 began a series of bombing raids on North Vietnam known as “Rolling Thunder,” with the intention of bringing the Hanoi leadership to the bargaining table. An initial 3,500 ground troops were designated for combat rather than advisory duty in Vietnam; through incremental escalation, the number of U.S. troops in Vietnam grew to 184,000 by the end of 1965 and to 429,000 by the end of 1966.

As the United States geared up for war, young Americans sensed that there would be a return to the draft lottery. The National Committee to the End the War in Vietnam staged the first burning of a draft card in the United States in October 1965. After the Tonkin incident there was also turmoil in South Vietnam, where Nguyen
Khanh tried to exploit the new situation with a series of repressive decrees that led to riots in the street and a series of plots and counterplots until Nguyen Van Thieu and Nguyen Cao Ky grabbed power in the spring of 1965.

North Vietnam attempted to match the U.S. escalation with incursions by its regular army into the central highlands, but a setback with the battle of Ia Drang Valley in November 1965 curtailed the use of their regular army in favor of guerrilla tactics. Even so, at Ia Drang 240 Americans were killed and 450 wounded, sending a shocking signal to the United States that the war would not be won easily or on the cheap.

Most U.S./South Vietnam military activity after Ia Drang focused on three areas. First, search and destroy missions, a favorite of General Westmoreland, the head of U.S. forces in the country, were part of his attrition strategy to kill and capture Vietcong forces in the South. Second, “pacification” was the securing of the South Vietnamese countryside by means of a combination of military protection and development assistance. Finally, efforts were made to cut the Vietcong’s supply line that came down the Ho Chi Minh Trail, a dense network of forest paths running through Laos into South Vietnam. Although the CIA began to pick up evidence of enemy activity along the trail as early as 1959, the route was of limited value to the North until 1963, when at the behest of Colonel Bui Tin it was expanded to accommodate trucks and large movements of North Vietnamese regulars. The original intention of Rolling Thunder was to disrupt traffic on the trail, but the bombing raids did not have the desired effect because the North Vietnamese showed remarkable ingenuity in repairing damaged roads and bridges. Moreover, the United States’ use of toxic chemical defoliants such as napalm and Agent Orange along the trail and in other areas to cut back the dense brush and expose Northern forces had devastating effects on Vietnamese civilians; news of this bolstered the antiguerrilla movement in the United States, and protesters and police clashed violently at the University of Wisconsin in October 1967.

The United States attempted again to disrupt the supply network in January 1968 by setting up a fire base along the Laotian border near the town of Khe Sanh. The U.S. marines at the base soon found themselves under heavy attack from North Vietnamese regulars. Only in April did the siege finally end, after an incessant barrage of U.S. artillery and air strikes equivalent to five Hiroshima-sized atomic bombs. Khe Sanh served to distract U.S. attention from North Vietnam’s preparations for its largest and best coordinated operation of the war, lasting from January 1968 to July 1969. Known as the Tet Offensive because it occurred during the Tet Nguyen Dan (the Vietnamese name for the Chinese New Year), the operation had North Vietnamese troops driving to the center of South Vietnam’s seven largest cities and attacking thirty provincial capitals from the deep South to the DMZ. The goal of the attacks was to ignite a popular uprising that would result in the overthrow of the South Vietnamese government and withdrawal of U.S. forces. In the first days of the offensive several cities were overrun and a nineteen-man suicide squad managed to seize the U.S. embassy in Saigon for six hours before they were routed. In most areas the U.S. and South Vietnamese forces repulsed the attacks immediately, but in Saigon the fighting lasted almost a week and in Hue bloody house-to-house combat consumed the two sides for over a month. Eventually, Hue was recovered, and Westmoreland declared that allied forces had killed more enemy troops in the last seven days of fighting than the United States had lost since the beginning of the war.

Although North Vietnam’s military objectives had not been achieved in the Tet Offensive, the psychological impact on the American home front was considerable. Many U.S. citizens who had supported the war were shocked by the ferocity of the attack and concluded that the government was misleading them. Members of Johnson’s own cabinet began to turn against the war and resisted calls for more troops. Soon Westmoreland was replaced in Vietnam by Creighton Adams, and that same year, 1968, Johnson announced an “October surprise”—a complete cessation of all air, naval, and artillery bombardment of North Vietnam north of the twentieth parallel as a symbolic gesture to encourage the peace talks taking place in Paris. The Paris talks broke down eventually, as did Johnson’s fortitude. He chose not to run for president in the 1968 election, which was marred by intense antiguerrilla protests at the Democratic Convention in Chicago, and eventually won by the Republican candidate Richard Nixon, in part because of his “secret plan” to remove the United States from the war with honor.

THE WIND DOWN

Nixon’s secret plan rested on two pillars. First, “Vietnamization” consisted of the gradual strengthening of the South Vietnamese military until they could hold their own against the NLF and North Vietnamese Army. It was hoped that reducing the combat load of U.S. troops would lessen popular opposition to the war stateside. Second, Nixon’s foreign policy of rapprochement with both China and the Soviet Union, in the midst of the Sino-Soviet split, had the effect of limiting their assistance to North Vietnam.

The diplomatic success was undermined by the negative publicity surrounding two notorious events: the 1968 My Lai massacre, which occurred when a platoon led by William Calley killed several hundred Vietnamese women and children and burned a small town to the
ground; and the bombing of Cambodia in 1969, which was intended to destroy NLF sanctuaries and supplies hidden along the Cambodian border. The latter action prompted more protests on U.S. college campuses—four students were shot and killed by National Guard troops during demonstrations at Kent State University in Ohio. On the warfront, one unintended effect of the bombing campaign was to push Communist forces deeper into Cambodia, which destabilized the country and in turn may have encouraged the rise of the Khmer Rouge, who seized power in 1975.

In an effort to help assuage opposition to the war, Nixon announced on October 12, 1970 that the United States would withdraw 40,000 more troops before Christmas. But on October 30th, the worst monsoon to hit Vietnam in six years caused large floods, killed close to 300, left 200,000 Vietnamese homeless, and brought the war effort to a standstill. On January 15, 1973, citing progress in peace negotiations, President Nixon suspended offensive operations in North Vietnam, then followed with a unilateral withdrawal of U.S. troops from Vietnam. The Paris Peace Accords were signed on January 27, 1973, officially ending U.S. involvement in the Vietnam conflict. For their efforts, Secretary of State Henry Kissinger and North Vietnamese lead negotiator Le Duc Tho were awarded the Nobel Peace Prize. But the fighting in Vietnam continued unabated. In December 1974 the U.S. Congress passed the Foreign Assistance Act of 1974, thereby cutting off all military funding to the Saigon government and rendering the peace terms negotiated by Kissinger unenforceable. By 1975 the South Vietnamese army stood alone against the powerful North Vietnamese, and Saigon famously fell on April 30, 1975 when two tanks crashed through the gates of the presidential palace as South Vietnamese who had cooperated with the United States desperately tried to flee the country.

THE AFTERMATH
Vietnam became a unified nation after the war, but at a great cost in terms of human lives and infrastructure, and in 1975 it was one of the world’s poorest countries. Although the population still suffers effects of Agent Orange and unexploded ordinance, economic reform (Doi Moi) begun in 1986 has drastically reduced poverty from over 70 percent of the population to less than 20 percent and spurred impressive long-term growth throughout the nation. Foreign investment also has played a major role in Vietnam’s economic upturn, with an increasing amount coming from the United States after the normalization of relations in 1995. For South Vietnamese connected with the former regime, the end of the war was a time of fear and resentment. Many highly skilled and educated South Vietnamese fled the country at the fall of Saigon and for years after, severely depleting the nation’s human capital. The new Communist government promptly sent connected South Vietnamese to hard-labor camps for “reeducation,” many for several years. Persecution and poverty prompted an additional two million people to flee Vietnam as “boat people” over the fifteen years following unification. To deal with the severe refugee crisis in the 1980s and 1990s, the United Nations established refugee camps in neighboring countries to process them. Many of these refugees resettled in the United States, forming large Vietnamese American emigrant communities with a decidedly anticommunist viewpoint.

In the United States the war had profound psychological effects, dividing the American public over the contentious issues of the humiliating withdrawal, perceived inequities in the draft, the schism in society created by the antiwar movement, knowledge of the devastation wrought on an impoverished country, and, most importantly, a profound sense of distrust in government, as many Americans believed their elected officials had not been forthcoming about the difficulties of the encounter while young citizens died in unprecedented numbers. Civil military relations were damaged because many soldiers and officers believed a winnable war had been undermined by civilian leadership and politics, and politicians felt that a runaway military had supplied it with misleading reports about the success of operations (particularly pacification). Finally, the role of the media was forever altered by reporters, photographers, and television crews who delivered coverage of the war into American living rooms. Some would hold the media up as heroic truth-tellers; others would blame it for supplying fodder to unpatriotic war protesters.

VILLA, FRANCISCO (PANCHO)
1878–1923

The memory of Francisco (Pancho) Villa evokes contradicting sentiments. Villa has been extolled as a trustworthy revolutionary. He has also been vilified as a cruel, dishonest bandit. Nevertheless, Villa remains a significant figure in Mexican history. His memory remains alive through Mexican ballads known as corridos, poetry, and film. This article examines the life of Villa—the bandit and the revolutionary—and his contributions to Mexican political history.

Villa was born José Doroteo Arango Arambula on June 5, 1878, in the northern state of Durango. (In The Life and Times of Pancho Villa, Friedrich Katz states that baptism records show he was baptized as Doroteo Arango, while Francisco Caudet Yarza claims in Pancho Villa that he was baptized as José Doroteo.) Villa came from a poor background. His parents, Agustín Arango and Micaele Arambula, worked as sharecroppers on one of the largest haciendas in Durango. Villa’s father died when Villa was young. Consequently, Villa, the oldest of five children, had to work to support the family at the expense of a formal education.

Villa was a bandit by the 1890s. The reason he decided to live the harsh life of a bandit in the mountains of Durango is unknown. In his memoirs Villa recounts that he fled into the mountains of Durango when he was sixteen years old out of fear that he would be incarcerated for shooting and injuring Agustín López Negrete, the owner of the hacienda on which he lived and worked (Katz 1998, p. 3). Villa allegedly shot the owner to protect the honor of one of his younger sisters.

However, some biographers question whether or not Villa’s attack on the hacienda owner actually took place (Braddy 1948, p. 349; Garfias, 1985, p. 15; Katz 1998, p. 65). Celia Herrera, whose relatives had been killed by Villa, recorded that he became a bandit upon murdering a friend during an altercation (Katz 1998, p. 6). Regardless of its validity, the incident remains a part of Villa’s story.

Doroteo changed his name to Francisco, or Pancho, Villa as an outlaw. The new name was probably an adoption of the name of his biological grandfather, Jesús Villa, and changed to evade the federal army and state authorities in Durango. Legendary tales impart that Villa adopted the name of a famous bandit, Francisco Villa, who died after being severely injured during an attack by local citizens in the mountains of Durango.

The description of Villa’s life during this time has varied. Some individuals viewed him solely as a violent, ruthless bandit. Celia Herrera’s Francisco Villa ante la historia describes Villa as one who led a life of crime and vengeance in which he killed friends, beat women, and tortured those who refused to cooperate when he demanded their money (Katz 1998, p. 6). Villa admitted to killing many men in his memoirs but denied being a cold-blooded murderer. Rather, the men were killed in self-defense or out of retaliation for betrayal (Katz 1998, p. 5).

On the other hand, Villa has been perceived as a benevolent champion of the poor. His memoirs reveal that he had stolen money and given it to the poor, including family members. These altruistic acts earned him the label of “Robin Hood of the Mexicans” (Brandt 1964, p. 153; Caudet 1998, p. 35; Katz 1998, p. 7).

By 1910 Villa had transformed from a bandit into a revolutionary. Abraham González, the leader of the Anti-Reelectionist Party in Chihuahua, recruited Villa and a military leader, Pascual Orozco, into the revolutionary movement against President Porfirio Díaz (Katz 1998, p. 73). González’s decision to recruit an outlaw to support the revolutionary efforts of Francisco Madero remains questionable. Regardless, the revolution was successful. President Díaz was forced to resign after thirty years of dictatorial rule, and Madero became the president of Mexico. Villa earned a promotion to honorary general, and he fought against the counterrevolutionaries, led by Orozco, in 1912.

Villa was also an important figure in U.S.-Mexican relations. His relationship with the United States was initially amicable. The United States allowed arms to be smuggled to Villa in January 1914, and President Woodrow Wilson ended the U.S. arms embargo against Mexico shortly thereafter, which allowed Villa to buy ammunition legally from the United States (Katz 1998, p. 250). President Wilson even offered Villa political asylum in the United States in 1915 (Katz 1998, p. 535). These actions illustrated the United States’ confidence in Villa’s abilities as a leader.
The positive relationship between Villa and the United States took a turn for the worse by 1916, when Villa attacked Columbus, New Mexico. The reasons for Villa's attack remain under debate. A letter from Villa indicates that the attack was meant as revenge for an act of betrayal by President Wilson during his war against the troops of President Venustiano Carranza of Mexico (Katz 1998, p. 552). Whatever the reason, the attack caused Wilson to send American troops to Mexico to capture Villa and destroy his forces (Sandos 1981, p. 303).

Villa was murdered on July 20, 1923, while driving to a village in Chihuahua. Two weeks after Villa's assassination, Jesús Salas Barraza claimed sole responsibility for Villa's murder. He said he killed Villa on behalf of the many people in his district, El Oro, who had been victimized by Villa (Katz 1998, p. 773). Salas was sentenced to twenty years in prison on September 13 but was pardoned and released a few months later. No one else was accused or arrested for Villa's murder.

An examination of Villa's life reveals that he probably was neither the devil nor the angel that many chose to label him. Instead, he is a complex figure whose memory continues to flourish in both Mexico and the United States.

VINDICATION

“Vindication” describes a style of political and intellectual discourse that motivates certain social movements. Adherents of vindicationist movements believe that their group is undervalued by the broader society, and they seek to rehabilitate and elevate their collective reputation. Vindicationist rhetoric argues that the minority group possesses qualities and abilities that are equal to or superior to those of the dominant group and that the dominant group's prejudice against the minority is thus based on false premises. Vindicationism functions to motivate potential followers of the movement while simultaneously scolding the dominant group for failing to appreciate the admirable character and qualities of the people for whom the movement is advocating. Vindicationism is most commonly found in the ideologies of feminist movements and racial-ethnic nationalist movements.

An early example is Mary Wollstonecraft’s A Vindication of the Rights of Woman (1792), a pioneering feminist treatise. Mary Wollstonecraft argued on behalf of women's natural talents and abilities and held that women should not be measured according to essentially male standards. She asserted that men needed to change in order to end women's oppression. Many of the ideological roots of twentieth-century liberal feminism trace back to Wollstonecraft.

A significant strain of vindicationism emerges in early African American political writing. Black abolitionist David Walker's famous “Appeal” (1829) argued for the humanity and inherent rights of African Americans. Walker traces African American heritage back to ancient Egypt, whose cultural achievements demonstrate racial abilities equal or superior to those of whites.

Vindicationist ideology is also central to white Southern nationalism in the United States. Immediately following the Civil War, Confederate apologists began to recast the causes of the war, in what became known as the “Lost Cause” narrative. This narrative denies the role of proslavery ideology as a significant motive behind secession. Instead, it argues that “state's rights” were the primary instigating factor. This permits Confederate apologists to situate the secession not as a rebellion but instead as advocacy of core American values as expressed in the Constitution. The other major component of Lost Cause vindicationism is the argument that the South lost the Civil War because of the North's overwhelming numbers and resources, and not because of Northern soldiers’ superior bravery or tactical skill. Thus, for Southern
nationalists invested in the Lost Cause narrative, the Confederacy can be honored in historical memory not as a rebellion motivated by a dishonorable motive, not as a military failure, but as a noble Lost Cause whose ultimate purpose was to uphold the best of American values.

Lost Cause vindicationism found an organizational home around the turn of the twentieth century with the establishment of the United Daughters of the Confederacy (UDC). The UDC embarked on a number of educational and symbolic campaigns to cement the Lost Cause ideology in American historical memory. The early 1990s saw the foundation of the League of the South (LoS), an explicitly separatist southern nationalist movement. By 2005, the neo-Confederate nationalism of the LoS had also suffused the Sons of Confederate Veterans, a much older, larger, and wealthier organization.

Many vindicationist ideologies develop elements of supremacism. This rhetorical move begins with an essentialist argument, holding that we—the vindicated group—are essentially different from the dominant group. The argument then asserts that the differences between the dominant group and the vindicated minority demonstrate the minority’s superiority to the dominant group. The essentialist strain in contemporary feminism at its extremist fringes verges into female supremacism. The lesbian separatist feminism that emerged in the 1970s is the most prominent example.

The early black abolitionist David Walker argued that blacks “never were half so avaricious, deceitful and unmerciful as the whites” (1829). In the mid-twentieth century, Elijah Muhammad (1897–1975) preached to African Americans that they are divine, while whites are a race of devils that were created by an evil black scientist. Muhammad’s arguments persist today in the theology of the Nation of Islam. The group’s current leader, Louis Farrakhan, has said that “White people are potential humans…they haven’t evolved yet” (Raghavan 2000, p. B1).

The use of “vindication” among social scientists to refer to a particular expression of minority grievances begins with Wollstonecraft’s feminism. The most common application of the “vindication” adjective has historically been to describe African American political writings of the nineteenth and early twentieth centuries. However, a recent shift has emerged in the social science community’s use of the concept. Political scientists now apply the term “vindicationism” to attempts by the United States to remake the world to conform to American values. This body of research locates the origins of American vindicationism in the Spanish-American War of 1898 and traces it through subsequent foreign interventions by the United States during the twentieth century. The vindicationist approach to foreign policy reached a peak with the wars in Afghanistan and Iraq, as advocated and prosecuted by the George W. Bush administration and its neconservative advisors (McCartney, 2004).

**VINTAGE MODELS**

Capital goods that are constructed at different moments in time embody the state of technology at the moment of their construction, thus giving rise to the notion of individual vintages of capital goods. These vintages differ in intrinsic “productive quality” because of ongoing technological progress, just like different vintages of wine can differ in quality. The basic idea underlying a vintage model is that the potential of technical change as an idea can only be realized in practice by first incorporating that idea in a piece of machinery and subsequently using that machinery to produce output. Because technical change is therefore embodied in individual pieces of machinery and equipment, vintage models emphasize the fact that complementary investment has to take place in order to realize the productivity promises of new ideas. There is also technical change not linked to investment that comes in the form of new ideas about the organization of production; this is called disembodied technical change in a vintage context. By contrast, an aggregate production function, which is still the most popular way of representing tech-
nology in large-scale macroeconomic models, assumes that capital is homogeneous and that the process of technical change can be represented as a continuous shift of the per capita production function that is independent of the rate of investment. Hence, all technical change is thought of as disembodied, and technology-induced reductions in unit production costs are therefore assumed to be independent of the actual level of investment.

The main focus of a vintage model is on the diffusion of technical change as opposed to endogenous growth theory that focuses on the source of technical change. The embodiment of technical change results in a capital stock that is heterogeneous in terms of the factor-productivity (hence the unit operating cost) associated with individual vintages. Depending on the type of vintage model on hand, the arrival of new superior technologies may render the old ones obsolete, leading to the economic scrapping of inferior equipment. It is through investment and disinvestment at both ends of the vintage spectrum that the average productivity characteristics of the capital stock can be made to change, though only relatively gradually.

Since the arrival of vintage models in the late 1950s and 1960s (see, for example, Johansen 1959; Salter 1960; Solow 1960; Phelps 1962, 1963; Jorgenson 1966; Solow et al. 1966), they have been used by economists interested in the connection between technical change and economic growth, because they highlight a number of important insights regarding the complementarity between productivity growth and investment. Firstly, productivity growth is positively influenced by gross investment. In the aggregate production function approach, labor productivity growth is as much the result of the growth in capital per capita (and is therefore linked to net investment per capita rather than gross investment) as it is the result of (labor-saving) technical change itself. Secondly, vintage models stress the idea that technical change has to be bought and paid for, rather than falling freely like “manna from heaven.” Consequently, anything that reduces incentives to invest in new machinery—for example, increasing uncertainty or a higher user cost of capital—will reduce the speed of diffusion of technical change. Thirdly, under the embodiment assumption, the average productivity characteristics of the total capital stock will change only gradually as new capital goods fill the gaps left by the technical decay and economic scrapping of old capital goods. Hence, if one wanted to change the average characteristics of capital stock in a noticeable way, one would either have to engage in nonmarginal replacement investment, or start promoting investment in new technologies sooner rather than later.

There are different types of vintage models, ranging from putty-putty (Solow 1960; Phelps 1962), to putty-clay (Johansen 1959; Salter 1960; Phelps 1963), to clay-clay models (Kaldor and Mirrlees 1962; Solow et al. 1966). Even putty-semi-putty models exist (Fuss 1978). The somewhat far-fetched names come from the world of pottery (Phelps 1963). The term putty refers to clay that is still soft enough to change shape, whereas clay refers to the hard-baked state of that shape that cannot be changed anymore without breaking it. When applied to a technology, putty-ness describes a state in which there are many different techniques associated with a specific technology that one could choose to implement, whereas clay-ness implies that there is just one implementation of a technology available, and that it is impossible to change it without “breaking” it and, thus, effectively discarding it. The first word (putty or clay) in the name of a vintage model refers to the size of the set of potentially available techniques before the moment that the actual hardware embodying the technique is installed (i.e., ex ante), and the second word (putty or clay) refers to the set of techniques still left after installation (i.e., ex post). A putty-clay model, therefore, covers a situation with (infinitely) many choices ex ante, and just one ex post (i.e., the one technique that has actually been implemented after making a choice from many techniques ex ante). Putty-putty models have infinitely many choices ex ante and ex post. A clay-clay model has just one technique to choose from, both ex ante and ex post. The putty-clay model is generally considered to be the most realistic vintage model because it recognizes that one generally has several production techniques to choose from, but also that once the machinery has been built and installed the choice for that technique can not be undone. Ex post “clay-ness” therefore represents the impossibility of reversing decisions made ex ante.

This irreversibility of investment ex post implies that one would have to try to forecast changes in factor prices ex ante, and incorporate these forecasts into the factor proportions that are to be embodied in the new vintage under consideration. For example, a rise in wages not properly foreseen would result in a labor intensity of production ex ante that is too high (with hindsight), and that would lead to an economic lifetime that is consequently too short (the economic lifetime of a vintage is equal to the duration of the period over which it would be most profitable to operate that vintage; see Malcomson 1975). In putty-putty models, such lifetime effects of forecasting errors do not exist, as one can continuously and costlessly adjust factor proportions (i.e., production techniques) to the current factor price situation on every vintage installed, from the newest to those installed in the distant past. Obviously, the latter situation is less relevant in practice, even though elegant in theory.

From a policy point of view, the irreversibility of investment is important, as it implies that humanity’s trust in technical change to solve some of its problems—
for example, global warming—may involve high investment costs. The latter are routinely ignored in an aggregate production function setting, as technical change is assumed to take place regardless of the level of investment. Consequently, an aggregate production function approach would tend to underestimate the real cost of technical change while neglecting the positive link between the effective pace of technical change (insofar as the latter is embodied in machinery and equipment), and the rate of investment. In a putty-clay setting, on the other hand, a large volume of replacement investment would be required to change the energy consumption characteristics of the aggregate capital stock in a nonmarginal way. Thus, either one would be forced to bear very large (just-in-time) adjustment costs, or, from a risk-diversification point of view, one would have to promote investment in new energy-saving technologies sooner rather than later. Interestingly, Schumpeterian endogenous growth theory (see, for example, Aghion and Howitt 1998) points out that the expectation of new technological breakthroughs that might or might not arrive just in time may actually have the opposite effect—namely, the postponement of investment. In any case, the embodiment of technical change in combination with the irreversibility of investment underlines the potential role of policymakers in reducing adjustment costs and smoothing transition shocks that are largely ignored in aggregate production function settings.

VINYL RECORDINGS

Vinyl is more than simply a material used to make disc records; the term is shorthand for a culture, a lifestyle, a set of attitudes about music technology, even an object of obsession and addiction. Vinyl, specifically polyvinyl chloride (PVC), became the standard material in the manufacture of records with the introduction of 33 1/3 and 45 RPM discs in 1948, replacing the shellac 78 RPM records that had been in use since the 1890s. The vinyl record remained standard until the 1980s and early 1990s, when it was largely replaced by the compact disc (CD).

Although relegated to the margins, vinyl continues to hold a special place for a certain segment of listeners and performers in the twenty-first century. Listeners value vinyl records both for their sound and as objects to be collected. Many audiophiles claim that the “warm” analog sound of a pristine record played on a fine turntable is superior to the “cold” digital perfection of any compact disc. The appeal of records, however, is perhaps more a function of their materiality than their actual sound. With the invention of the record came the advent of record collecting, and soon after came the obsessive collector who seeks rare or unusual records with extreme devotion. In the 1920s the “disease” known as “gramomania” (derived from “gramophone,” the British term for phonograph) was facetiously identified, and “vinyl addicts” continued to figure in the popular imagination throughout the century (e.g., in Nick Hornby’s 1995 novel High Fidelity and its eponymous film adaptation in 2000). Although such “addicts” represent a small fraction of those who collect records, their example reveals that there is more to vinyl than simply music. Record collecting is about the thrill of the hunt, the accumulation of expertise, the display of wealth, the visual and tactile sensation of artifacts, and the creation and cataloging of memories.
A certain type of musician—the disc jockey (DJ)—also values vinyl, not simply as a means for reproducing existing sounds, but for creating new music. DJs are often thought to do little more than play records, but the ways in which many hip-hop and electronic dance music (EDM) DJs in particular manipulate records elevate them to the status of musicians. DJs may combine the sounds of multiple records, alternate between discs in complex counterpoint, or “scratch” them (move them back and forth underneath the stylus), all of which can create new sounds not contained on any single one of the manipulated discs. EDM DJs often combine dozens of individual songs into a seamless musical flow that may last several hours, while hip-hop DJs (also known as turntablists), may take a single passage from a record and manipulate it into an extended composition.

The standard equipment for most DJs has been two turntables and a mixer (a machine that regulates the signal being sent from the two machines to the speakers). In the 1990s, however, various companies began developing and refining CD turntables. The advantages of these players are clear. It is a much simpler matter to find, repeat, and shape particular recorded passages than with traditional turntables, and one need not worry about replacing cartridges or wearing out records. (With digital turntables, the DJ manipulates a simulated record platter, whose movements—even scratching—are converted into signals that transform the sound of the CD.) Moreover, with inexpensive CD burners, DJs can easily compile their own individualized records from other CDs or from digital files, such as MP3s.

Despite these advantages many DJs have resisted the incursion of CD turntables. This resistance is strongest among hip-hop DJs, and can be explained with a single word: vinyl. Because vinyl was present at, and largely responsible for, the birth of hip-hop (which developed around the art of the DJ), it is considered a precious substance, one that carries with it the whole history, the DNA, of hip-hop. Moreover, with traditional turntables, the DJ handles the sound directly, essentially touching the music; CD players remove the immediacy and tactility of vinyl. Nevertheless, as CD turntables continued to improve in the early 2000s, DJs increasingly began turning to digital machines. Some have argued that DJing transcends vinyl and must evolve with changing technologies.

In the early years of the new millennium, vinyl finds itself both cherished and embattled. It continues to be collected and manipulated, and coexists, sometimes uneasily, with digital technologies. Although it plays an important role in the lives of many listeners and performers, its place in the musical life of the future is uncertain.

Mark Katz

**VIOLENCE**

Though violence has been characterized as the use of force by and against one or more social subjects with the intention to inflict bodily harm, the study of violent processes over the past three decades has broadened the concept by underscoring its varying forms, which emerge from the struggle for power between modern states, elites and subalterns, and recently formed communities. Interstate war, discourse and the coercive apparatuses of the state, epistemic violence, ethnic conflict, collective recovery, and terrorism represent intellectual signposts in the scholarship on violence, although they emerge from different trajectories of inquiry that do not belong to a single genealogical tradition or discipline.

**WAR, THE STATE, AND COERCION**

Violence is identified as an effect of competitive war-making in early modern Europe, which produced a bureaucratic apparatus that could secure the material and human resources required for managing warfare. Such bureaucratic apparatuses would form the institutional skeleton of modern national states from the seventeenth century onward (Tilly 1990). The link between war, the state, and violence is reflected in Max Weber’s remark that a striking feature of the modern state is, ideally, its “monopoly of the legitimate use of physical force” and, therefore, its ability to sanction the use of force (Gerth and Mills 1946, p. 78). However, this is not to say that modern states only seek to stem forms of unsanctioned violence, especially those that appear to threaten its authority. Michel Foucault’s
inquiries (1963, 1966, 1975) reveal that modern welfare states also strive to redefine, regulate, and channel the use of force in order to achieve social order. This insight marked a watershed in the study of violence and shifted the focus of research on the phenomenon from interstate war to the subtle manners in which coercion and the "measured" use of force are deployed by state agencies in order to shape the social identities of individuals. Foucault's studies of institutions of criminal punishment and rehabilitation, schools and hospitals, and the spaces of economic production underscore the discourses that organize these institutions, in order to socially produce docile subjects whose utility would, ostensibly, advance societal welfare and maintain order. Competing legal, penal, medical, and academic disciplines converge to define, discursively, what forms of violence are criminal, why they are socially immoral or harmful, and how their perpetrators should be punished or rehabilitated. Far from remaining ideological platitudes that are applicable only to those labeled as "criminals" or "insane," these social meanings of deviance are authoritative because they are articulated as categories of objective knowledge, and they become a metric by which to measure—and curb—our own deviant and violent tendencies. Foucault not only demonstrates how social control is achieved from above, he also reveals the political utility of microdimensions of violence, which enable the reproduction of a predictable social order by conditioning individuals to coerce themselves through conformity to institutionally sanctioned categories of "normal behavior."

Ironically, the very institutional apparatuses and discourses that seek to discipline subjects can also be the source from which to innovate new strategies for resisting violent and coercive regimes. Studies of collective violence associated with popular revolution in western Europe, for example, reveal that tactics employed by protesters borrowed heavily from the police forces' own methods of employing violence to suppress collective protest. Similarly, these investigations also point to the manner in which episodes of collective violence directed against monarchical power were morally legitimated by perpetrators through the appropriation and redeployment of political concepts like popular sovereignty. Anthropologists, historians, and sociologists attentive to the discursive dimensions of collective movements enrich the meaning of the concept of violence by tracing the manner in which knowledge, as a means of exercising social power, can animate and constrain collective forms of resistance that employ the use of force.

***EPISTEMIC VIOLENCE***

Inquiries into the creation of social order under European colonization identify epistemic forms of violence that radially essentialized social identities and dismantled previously existing social solidarities. This body of literature marks a departure from a previous form of anthropological study that accepted the "traditional culture" of non-Western societies as an essentially differentiating feature and one that necessitated methods of exhaustive description as a form of analysis. Anthropologists and historians interrogating the cultural objects of "tradition" demonstrate that in the name of crafting effective procedures of political rule, colonial administrators set about to objectify "native traditions." Such a project involved the production of systematized bodies of objectified knowledge that documented the "cultures and traditions" of colonial subjects; rather than learning about their dynamism, the European project reduced their complexity and then enabled their ossification (Cohn, 1987, 1996; Dirks, 1987, 2001; Chatterjee, 1986, 1993). Working with Orientalist assumptions about "the traditional East," these bodies of knowledge taxonomically classified categories and practices of social identity in new and singular relationships with Western notions of religion, ethnicity, or clan. Importantly, the concept of violence in this domain of research is considered a historical process that involved supplanting the previously existing "fuzzy" character of social identity, which was shaped by numerous sources of competitive influence, with rigid conceptions of identity (Kaviraj 1992, p. 20).

Having epistemologically fixed such "traditions" as the primary source of native identity, colonial rulers applied these taxonomies to form key state undertakings spanning law and policing, education, urban planning, the fine arts, and census-taking operations. State projects aimed to stabilize the colonial state's task of maintaining social order, creating the conditions for profitable and tax-able economic production, while representing—ostensibly—only a latent imposition on the social and cultural practices of colonial subjects. In fact, these brutal processes of colonial rule would engender more violent social transformations and political conflicts.

***COMMUNAL AND ETHNIC CONFLICT***

Institutionalizing such rigid conceptions of identity in the state's operations created the conditions for political forms of violence by sharpening—and rendering incommensurable—the perceived cultural differences between novel "traditional" communities that consequently began to form. This was especially palpable in the context of emerging native leaders who were able to cultivate new supportive constituencies, in terms of their imagined traditional commonalities, and call for the state to arbitrate when conflicts with rival communities arose. As historians of colonial Asia and Africa demonstrate, despite the state's
quest to maintain social order, communal and “tribal” conflict became a bloody and conspicuously recurring phenomena in this era.

The emergence of competing traditional communities became a mobilizational resource—and source of tension—when native elites began to organize collective resistance to colonialism. Such communities were rallied behind the call for national sovereignty through movements of cultural nationalism. For native elites, political independence was a corresponding entitlement of these traditional communities who now aspired to the status of nationhood. Of course, such cultural forms of nationalism were riddled with tensions, often manifesting in violent internal conflict. Though statehood was eventually achieved for most colonies, the process was often characterized by territorial partition, bitter campaigns of violence, and the unprecedented displacement of people (as in the case of India and Pakistan). In other instances, the hollowness of constitutional arrangements based on “multiculturalism” was exposed when domestic politics spiraled into intense ethnic violence or agonistic competition over political and economic resources. Such violence emerges historically out of—and through—the commission of epistemic forms of violence.

COLLECTIVE INJURY AND TERRORISM

The study of violence associated with contemporary episodes of ethnic cleansing and genocide has revealed much about the dynamics of collective recovery. Scholars in this subfield have shown how testimonies relating to experiences with violence are often shaped by an implicit requirement that frayed ethnic or national solidarities be restored. Testimonials are burdened with the tasks of reestablishing familial-communal honor, identifying perpetrators, and securing state resources for communal rehabilitation. Strikingly, the analysis of collective memory and recovery points to the difficulty of articulating pain as an experience and how the depth of it is necessarily reduced when it is articulated as a collective and social form of suffering (Das 1997).

The theme of collective injury is also salient to discussions of more recent forms of violence associated with terrorist groups, particularly those movements that seem to be morally organized by a religious ethos. Scholars have shown that the moral justifications employed by such movements draw upon earlier forms of cultural nationalism that challenged foreign occupation and imperialism, as well as “heretical” regimes and moral “waywardness.” Many current-day militant movements draw their moral authority from religious reform movements from the colonial era that placed an emphasis on the correct observance of religious rituals. The Taliban, for example, trace their genealogy to the Deoband movement in late-colonial-era India, which initiated and institutionalized the madrassa-based study of Islamic law and the upholding of Muslim ritual practices (dress, morality, and regular prayer) as a means to achieve a virtuous way of life.

Tellingly, the focus of such religious reform movements was transformed during the Cold War period when “insurgents” were recruited, trained, and armed by alliances of Western states and their clients to fight “communism.” Militant and globally dispersed movements that turn noncombatants into targets of political violence are the products of proxy wars that were waged between the superpowers in Asia, Africa, and Latin America.

In summary, the study of culture and ideology has transformed the meanings of violence by shifting away from an emphasis on interstate war and physical harm to an exploration of the more insidious ways in which highly regulated forms of violence and coercion—presented as socially productive methods of reform and development—are sanctioned by the state in order to govern the actions of individuals. Examinations of the formation of discourses, as loci in which social power is exercised through claims to disciplinary knowledge and truth, reveal how epistemic forms of violence reduce the complexity of social identity and, in the colonial sphere, artificially classify non-Western societies as premodern. Ironically, the history of nationalist and political movements from the end of European colonial rule through the Cold War and afterward is marked by forms of communal and ethnic conflict that reinforce the social and political salience of tradition. Terrorism—and the predominantly Orientalist public debate surrounding it—is a contemporary example of the ways in which religion and politics can come to be mutually dependent and, moreover, of how many of the most dynamic cultural and logistical strategies that organize violence rest outside the domain of the state.

Violence, Frantz Fanon on

According to the Martinican author and political theorist Frantz Fanon (1925–1961), violence fundamentally defined the meaning and practice of colonialism, and as such violence was central to the effort to resist and overthrow colonial rule. For Fanon, violence was both the poison of colonialism and its antidote.

Fanon arrived at this view on violence largely through his work as a psychiatrist. He was born in Martinique and trained in France, later working in a hospital in Algiers, the capital of Algeria, under the auspices of the French colonial administration. Most of his psychiatric patients were native Algerians, many suffering from the mental and physical turmoil of colonial degradation, including the experience of torture at the hands of French interrogators. Some of these French torturers were also his patients, and by working with them Fanon learned how the “disease” of colonialism also infected the mind of the colonizer. Beyond the hospital walls, Fanon saw how the constant presence of French police stations and military barracks conveyed to the Algerians the clear message that they were little more than animals, to be beaten, dehumanized, and contained for the sake of colonial interests. He thus gained first-hand knowledge of the damage that colonialism inflicted on the minds and bodies of African people.

On November 1, 1954, leaders of the embryonic Algerian national movement, known as the Front de Libération Nationale (FLN), began the armed struggle for independence with violent attacks against French military
and civilian targets, thereby rejecting the path of negotiation and compromise that had been followed to this point. His experiences treating the sufferings of Algerians and witnessing this explosion of violent anticolonialism led Fanon to join the nationalist movement and advocate for the Algerian revolution as a militant activist and writer. He resigned his post at the hospital in 1957, unable to tolerate working for the colonial administration any longer.

Fanon's clearest and most thorough articulation of his views on colonialist and anticolonialist violence can be found in the chapter "Concerning Violence" in The Wretched of the Earth, published in 1961, his last work before his death. In it, Fanon argues that anticolonialism must be revolutionary rather than reformist. Colonialism, he explains, is "not a thinking machine, nor a body endowed with reasoning faculties. It is violence in its natural state, and it will only yield when confronted with greater violence" (Fanon 1963, p. 61). Since violence fundamentally defined the colonizing society’s existence, only "absolute violence" could get the colonizers’ attention. Absolute violence meant that no meaningful distinction was to be made between the French civilian settlers in Algeria and the French police and military forces. According to Fanon, they were all complicit in some way and thus all subject to anticolonial violence. This view of colonialism reflected Fanon’s Manichean understanding of the relationship between the colonizers and the colonized. The two were as opposed as white and black; in fact, they were white and black, and no middle ground or negotiated withdrawal was possible if the colonized were to ever be truly liberated. True liberation could only arrive when the binary categories of white and black were destroyed, expunged from the earth.

Fanon believed that anticolonial violence was required in order to achieve two intimately connected objectives: the expulsion of the colonizer and the mental “decolonization” of native Algerians. To Fanon, this latter aim was fundamental because institutional independence from the colonizer would mean little if the people remained psychologically trapped within a self-image as colonized, dehumanized objects. Fanon observed that Algerians were indeed violent under colonial rule, but this violence was directed toward other Algerians as an expression of self-hatred in which “black-on-black” violence represented a futile effort to negate the dehumanized identity imposed upon them. In the movement, led by the FLN, to redirect this violence toward the colonizer, Fanon conceived of a way to construct and affirm a positive political identity infused with a national consciousness liberated from the colonized mindset: “At the level of individuals, violence is a cleansing force. It frees the native from his inferiority complex and from his despair and inaction; it makes him fearless and restores his self-respect” (Fanon 1963, p. 94).

Individually and collectively, anticolonial violence for Fanon was an act of rebirth—“the veritable creation of new men” (Fanon 1963, p. 36)—that simultaneously bound the people together in an expression of national solidarity in which all are implicated in the struggle. Thus, violence was to shape the Algerian national consciousness as the people became collectively responsible for, and thus asserted popular authority over, the anticolonial struggle itself and its immediate product, an independent nation built upon socialist principles and institutions. Fanon argued that this expression of solidarity should not end at the national borders; the anticolonial struggle united the African continent as a whole, as Africans looked forward to the unique and varied postcolonial contributions that they would make on the world stage.

**VIOLENCE, ROLE IN RESOURCE ALLOCATION**

Violence, or the threat of violence, is a source of political and economic power, a means of acquiring either assets, income, or influence over their use and distribution. It is, however, not the only source of power, though perhaps it is the most familiar.

Simple acts of violence, such as robbery, can achieve short-term gain, or they can achieve long-term gain by setting precedents to support future threats. Well-established threats are the basis for systems of tribute or “protection money.” The difference between these two approaches is that robbery is typically furtive, making use of stealth to compensate for a lack of real superiority in force. In contrast, a tribute system is public to the extent...
that the violent agent is confident of superiority in force, so that general knowledge of the threat offers little protection for others and instead increases income from collections. What the two approaches share in common is that violence can take the crudest forms and be effective, since the goal is to acquire finished goods without involvement in the production process.

If the use or threat of violence is to be involved in the actual process of production, matters get more complicated. The goal shifts from collection to coercion, and both the exercise and threat of violence need to be more carefully calibrated parts of a program of supervision, as in the case of slavery and other forced labor systems.

A great many societies until recent times, including most colonial regimes, have had economic arrangements centered on threats of violence in order either to collect finished goods and money as tribute or to coerce labor services.

In modern capitalist societies, violence continues to play a role in the defense of property and enforcement of contracts, but under normal conditions it remains in the background while the law occupies the foreground. Violence seems to have played a key role in the acquisition of property during the centuries preceding the modern era, a process sometimes referred to as “original accumulation.” It still can play that role during periods of war or other severe crisis, but this use of violence is rarely acknowledged as a regular part of modern economic arrangements.

Critics of violence, in every social arrangement from ancient to modern, point to the suffering and destruction it causes. Some simply insist that no countervailing benefit could ever compensate for the horrors of violence, and they push at every juncture for its elimination. Others argue that both the destruction caused by violence and the parasitism of those who live off acts of violence constitute economic waste.

Apologists of violence usually claim that its elimination is an unachievable dream and that the best hope lies in channeling it instead, at least to minimize harm but possibly to do some good. To those who decry its economic wastefulness, they reply that this waste is more than compensated for, insofar as it leads to additional productive activity. In a world where most people are viewed as wasting time—and this is a view that many colonial rulers had of their subjects—apologists can argue that unless rulers’ demands for tribute or labor are excessive, little more than this wasted time is actually lost, while production in the meantime is increased.

Perspectives on violence can depend somewhat on what theories people hold on how it arises. In classical economic theory, competition for scarce resources can give rise to violence in the form of wasteful strife and warfare. In this view it is desirable and efficient to develop a state structure with a monopoly on violence—as Thomas Hobbes most vividly advocated in Leviathan (1651)—and to use it to build a legal system of property rights and contract enforcement that encourages resource allocation through markets instead. Böhm-Bawerk (1914) painstakingly showed that once property rights are secure and contracts enforceable, introduction of additional force in an effort to control market dynamics was futile and wasteful, and this has been the neo-classical view ever since.

In certain political realist theories, such as those of Eugen Dühring (criticized by Friedrich Engels in Anti-Dühring, 1894) in the last century, violence arises more from its own profitability: The resources expended in a violent campaign to extract goods or labor yield a return as good as or better than from any other use. Because property rights and contracts are not here assumed to be firmly established, this in itself would not contradict the classical view, but political realists go further to argue that violence can be efficient also on the macro level, primarily because of its function in extracting productive labor from people that otherwise would not have been performed. According to those views, the state with its monopoly on violence contributes to economic activity by institutionalizing the labor extraction function, leaving to the market a decidedly secondary role of efficiently allocating resources thus extracted. Perhaps where land and resources are abundant and hard to dominate, a property system might be inferior to a tribute or slave system in terms of productivity.

Georges Sorel (1906) explored the potential for violence to liberate the oppressed, suggesting that the huge problem of organization could at least in principle be overcome by a general strike of all workers. According to him, the general strike, constructed as a myth as well as organized as much as possible in reality, represents the socialist answer to oppressive violence from above.

According to other theories, including certain psychological views, such as those expressed by Sigmund Freud in Civilization and Its Discontents (1930), most violence cannot be accounted for by either of the above economic theories. Roughly put, violence instead arises from protracted and intense frustration brought about by all kinds of social experience, such as role conflict or inhibition of biological impulses, and it is best understood as an expressive rather than instrumental phenomenon. In other words, in the view of these theories, rather than a rational act for gain, violence is a kind of lurch into irrationality engaged in by someone for whom no rational option appears.

Finally, some theories are inspired by biology, claiming that violent behavior that is irrational at the individual level might appear rational at the species level.
survival prospects of the species are enhanced even though those of particular individuals appear not to be, and therefore some mechanism of natural selection might breed in a certain amount of violent tendencies that could not otherwise be accounted for.

VIOLENCE IN TERRORISM

While there are many definitions of terrorism and no single accepted one, the research literature assumes three main components: (1) use or threat of violence; (2) injury to noncombatants; and (3) a symbolic effect designed to attract attention. Violence is an integral part of terrorism and is present in every incident.

Several factors influence the decision to use violence within the terrorism framework: (1) violence must be faced by the target power, and the target power’s response may violate its own values and draw criticism at home and abroad; (2) violence attracts attention to the terrorist organization’s agenda, obliging the targeted regime to confront the problems raised and try to solve them; and (3) the use of violence arouses fear and horror in the civilian population. The perpetrators of the violence try to make the population pressure the regime into solving the terror problem, and sometimes even to meet the demands of the terrorist group.

Even though terror is considered the weapon of the weak, it should be stressed that the use of violence in the framework of terror is also common between sovereign states, and not only between illegal groups operating against certain other groups or states. State terrorism is terror perpetrated by states against their citizens or via specific groups that enjoy state support, whether covert or overt. Totalitarian regimes such as that of Augusto Pinochet in Chile or Saddam Hussein in Iraq used their own secret police forces to terrorize their citizens. These regimes operated against their own citizens, employing kidnappings, torture, and extrajudicial executions. Other regimes, mainly in South America, had armed militias that perpetrated acts of terror against their citizens and which were supported or tacitly approved by the state.

Despite this reality, there is disagreement regarding the inclusion of state-sanctioned acts of violence against citizens in the definition of terror. The main dispute concerns the fact that state violence instigated in its own territory is considered legitimate and justified in the struggle against hostile elements, and therefore cannot be defined as terror. The significance of this is that the definition of state-sanctioned acts as terror depends on the attitude of the international community toward the methods used by the state, the conditions under which the violence is used, whether in an armed conflict facing the state or during peacetime.

According to David Rappoport’s 2003 work, there have been four separate waves in the use of terror since the 1880s. The first lasted about thirty years, from the 1880s to the 1920s. The groups active during this period espoused a revolutionary antimonarchy ideology, using force mainly in assassination attempts against representatives of the royalty; for example, the People’s Will, Narodnaya Volya in Russia, or the Black Hand in Serbia. Notable among the events of this period were the assassinations of Czar Alexander II by Russian revolutionaries on March 13, 1881, and of Franz Ferdinand, heir to the Austrian throne, on June 28, 1914, the incident that sparked World War I.

The second wave continued from the 1920s to the 1960s. In this wave, terror was used mainly by ethnic groups in their struggles for independence from colonial powers—the EOKA in Cyprus and the Etzel and Lehi, Hebrew acronyms for National Military Organization and Fighters for Israel’s Liberty, respectively, in British Mandate Palestine. The activities in this second wave differed from those in the first wave in that their targets were
military and government installations, similar to the guerrilla warfare of the Force de Libération Nationale (FLN) in Algeria in the mid-1950s.

The third wave was concentrated in the 1960s and 1970s and was employed by ideological groups on the radical left trying to change the ruling regimes in their own countries, like the Red Brigades in Italy. For the first time, these groups were active in countries other than their own. They cooperated with like-minded foreign organizations and for the first time launched international terrorist activities, such as when the Palestine Liberation Organization (PLO) cooperated with the Japanese Red Brigade in Jordan, Lebanon, Israel, and Libya, among other countries.

The fourth wave began in the 1980s. The political ideology of the 1960s and 1970s has been largely replaced by religion as a background for acts of violent terrorism and its targets. Most perpetrators come from Islamic countries, although today’s terrorism is not unique to Islam. The main tactics are kidnappings and suicide attacks in numbers that rose from 40 in the 1980s to 125 in the 1990s, and dozens of attacks per year since 2000. The most notable terrorist group is Al-Qaeda, which recruits and operates worldwide. Its network-based structure and use of the Internet for communication between cells in different countries make it completely different from the typical groups of previous decades.

In the early twenty-first century accelerated technological development and computerization throughout the world have increased terror that is less conspicuously violent, such as cyber-terrorism. This involves attacks against a country’s computer systems and civilian and military communications. As such, researchers are not in agreement as to whether this is actually terrorism, since it does not involve violence.

VIRGIN OF GUADALUPE

SEE Symbols.

VIRGINS

Virgins are individuals of both sexes who have never had sexual intercourse, most commonly defined as vaginal penetration. Historically, virginity—particularly female—has been important in many cultures. The virginity of a bride has often been regarded as a mark of her purity, a sign of her family’s honor, and as a means of guaranteeing the passage of her husband’s bloodlines to her children. For Christians, male and female virginity has long been associated with spiritual purity, and most Christian religions today still place a high value on premarital virginity, even in societies where the vast majority of individuals do not remain virgins until marriage. In many contemporary societies, particularly in Africa and the Middle East, premarital female virginity still has tremendous cultural significance. In other cultures, especially North American and European societies, it is uncommon for people to remain virgins much past late adolescence. However, in such societies, there remains a double standard that encourages women to remain virgins longer than men.

In the United States, contemporary definitions of virginity are fluid. Some regard any sexual activity short of vaginal penetration as compatible with maintaining virginity, whereas others believe that participation in oral or anal sex constitutes a loss of virginity. Although heterosexuals are more likely to link virginity to vaginal penetration, most homosexuals do not consider those who have engaged in oral or anal sex to be virgins. For some, whether one gives or receives oral sex affects the potential loss of virginity. Similarly, in the case of anal sex between two men, there is sometimes debate as to whether one must penetrate or be penetrated in order to lose one’s virginity.

In most cases one’s status as a virgin is linked to lack of experience with certain sexual activities. In some instances, however, virginity is more closely tied to emotional or spiritual definitions. Some men and women, including many victims of rape, do not believe that non-consensual sexual intercourse can be counted as losing one’s virginity. Certain Christians who, after losing their virginity, decide to abstain from sex before marriage, consider themselves to have regained their virginity, becoming “born-again virgins” and thereby tying the notion of virginity to a personal spiritual state rather than a physical act.

In the United States today, loss of virginity is much less likely to be considered medically than emotionally or physically. In many cultures (and in earlier U.S. history), however, loss of virginity has been associated with the breaking of the hymen, a ring of tissue partially occluding the vagina. Though there is no necessary correlation between virginity and an intact hymen, some women have opted to undergo vaginal reconstruction surgery, which repairs or replaces the hymen. Although some do equate

SEE ALSO Al-Qaeda; Guerrilla Warfare; Terrorism; Violence
this procedure with a restoration of virginity, many others believe that restoring the hymen cannot make one a virgin.

Female virginity has long been of great importance to many cultures. Anthropologists suggest that a society’s attitude toward virginity is an indication of the social roles of men and women: In traditional, patriarchal societies a woman’s virginity is often considered a commodity that enhances a woman’s desirability, enables a prestigious marriage, cements interfamily alliances, and ensures the legitimacy of heirs. In the Kanuri society of Africa virginal brides were considered more prestigious than older, divorced women because they were believed to be more submissive to their husbands. In China, well into the twentieth century, a bride’s virginity was thought to be something owed to her husband; a man would consider it beneath his dignity and honor to wed a woman who was not a virgin.

In societies that place a high value on virginity, ritual verification of a bride’s virginity were common; such tests persist in some traditional cultures. In many cultures throughout the world the virginity of a woman was verified on or before her wedding night. As late as the 1950s the bedsheets of Kurdish brides were examined after the wedding night, and a handkerchief smeread with hymenal blood was presented to the groom’s mother as evidence of the bride’s virginity. A bride who failed to prove her virginity was returned to her family, where she was killed. African Amhara women who were discovered to not be virgins on their wedding nights were returned to their families to be beaten. Brides among the Bulgarian Gypsies and the African Twi were required to present proof of virginity, in the form of stained bedclothes, to their husbands’ families after the wedding night. Bedouin men tested their brides’ virginity with togas wrapped around their forefingers. Though such rituals of virginity verification are rare in North American and European societies and disappearing in other areas of the world, some cultures, particularly in Africa and the Middle East, continue to practice them.

VISUAL ARTS

Art comes from the Latin word *ars*, meaning skill, thus the term visual arts describes those skills that are visible to the human eye, including drawing, painting, sculpture, architecture, graphic art, decoration, and later photography and film. The visual arts are the expression of human creativity, a visualization of the way we see life and the world around us. Standing midway between what is perceived and what is believed, they stem from a need to make sense of human existence and explain it, both internally and externally.

One of the earliest forms of communication, the visual arts form a language through which humans speak about the world. This language is tempered by the society from which it springs, conditioned by its beliefs, its rituals, and its social codes. Pablo Picasso’s painting *Guernica* (1937), for example, can be fully understood only when related to the environment of the Spanish civil war (1936–1939). Likewise, every work of art has to be rooted in its own context, which is what gives it shape, function, and relevance—only then is it truly alive. During World War II (1939–1945) a Nazi officer showed Picasso a reproduction and asked, “Is it you who did that?” Picasso is said to have replied, “No, it is you.”

HISTORY

It is believed that the history of the visual arts begins with sculpture, the creation of a three-dimensional form. One of the earliest examples was the Lion-Human of Hohlenstein-Stadel, Germany (c. 30,000 BCE), a fantastic form carved from mammoth ivory. Half human and half beast, it marks the meeting of external reality with internal reality, and is it at this juncture that visual art occurs.

The decorative arts have always served both an ornamental and a functional purpose. Originating with the daubing of the body, it was an impulse that led to the fashioning of jewelry, pottery, glassware, textiles, and furniture. By 7000 BCE ceramic ware was already in use, and as decoration became more skilled and sophisticated different types of materials were adopted to create all kinds of objects. One of the most skilled and intricate early pieces was the Great Lyre from Mesopotamia (c. 2550–2400 BCE), which was created in the form of a bull’s head. Combining gold, silver, lapis, shell, and wood, it was both functional and beautiful.

Some of the most important elements of the visual arts are drawing, the creation of an image, and painting, the application of color to a surface. At Chauvet, in southwestern France, there are caves full of early drawings and paintings of animals (dating from 25,000 to 17,000 BCE). A visual expression of the world in which early humans lived, these pictures depict the beasts that were hunted and worshipped, and whose bones provided tools and
weapons. Located far away from the living area, in the darkest part of the caves, these paintings evidently had a ritual and symbolic purpose. It is clear that both images and pictures were once things of power and that art itself played an important role in the everyday struggle of living; only today has it been relegated to a purely aesthetic role.

Beginning with the cave, architecture—“the enclosure of spaces”—also dates back to prehistoric times. As skills developed and resources increased, architecture became a statement about religion, power, and spectacle. The giant pyramids of Giza (c. 2601–2515 BCE) were the forerunners of today's skyscrapers. Soaring toward the heavens, they proclaimed the divine status of the pharaohs and glorified the wealth, prestige, and stability of Egypt's rulers. At 792 feet high, the Woolworth Building in New York (1911–1913) is almost twice the height of the tallest pyramid, yet the message it sends out is much the same. Built not from brick, but from steel, glass, and concrete, like the pyramid, it dominates the skyline. Imposing a sense of order and control, it proclaimed the supremacy of the United States as the richest, most powerful, and most technologically advanced society on Earth.

Despite its importance, advanced or sophisticated technology was not an essential requirement for artistic achievement. Fewer resources did not mean lesser skill. Although they did not use iron or steel, the Moche people of ancient Peru (200 BCE–600 CE) were exceptional potters and metalworkers. The Moche potters were renowned for making vessels in the form of human heads. Many of these heads are strikingly true to nature, and they show a mastery of the human face.

This highlights the fact that the development of the visual arts is not primarily a story of technical progress but a story of changing ideas. Each culture had its own idea of the world. This was embodied in images and structures that were far more potent than words could ever be.

For a long time art reflected the domination of knowledge over vision. Based not on what artists could see at any given time, it was conditioned by what they knew was there. It was the Greeks who first began to use their eyes, as their sculptors, artists, and craftsmen began to rely more and more on what they could see, feeling free to represent nature and the human body the way they saw it. This transition from knowledge to the visual marked the beginning of innovation.

In Europe, it was during the Italian Renaissance (fourteenth through seventeenth centuries) that the visual arts really began to mirror a fragment of the real world. The adoption of scientific perspective, the knowledge of anatomy, and the rediscovery of the inheritance of Greece and Rome added to the armory of artists, helping them master the portrayal of nature and enabling them to represent the world around them. Led by Leonardo da Vinci (1452–1519), artists began to explore the visible world, experimenting and searching nature as a means of deepening their understanding.

CHINA

In China principles of theory and aesthetics were formulated as early as 500 BCE by the scholar Xie He (500–c. 536). The emperor himself practiced painting, and schools were developed where art was taught as a subject. The first academy was established at the Song court in the early thirteenth century. The visual arts were thus placed on the same footing as the literary arts, and painters finally achieved a status equal to that of court officials.

The idea of art for art's sake was also well established in China, and a distinction was made between amateurs and professionals, between those who worked for money and those for whom personal expression mattered most. This philosophy was first articulated by Ni Zan (1301–1374), one of the most famous painters of the Yuan dynasty, who was the first to assert the independence of the artist: "What I call painting does not exceed the joy of careless sketching with a brush. I do not seek formal likeness but do it simply for my own amusement" (Bush and Shih 1985, p. 266).

POWER, PATRONAGE, AND PROPAGANDA

Artists had always worked for patrons and institutions who specified what they wanted and rewarded the artist accordingly. In eighteenth-century Europe the initiation of regular exhibitions where artists sold their work completely changed the traditional pattern. Instead of working for patrons, artists now relied on exhibitions to sell their work, appealing to critics, connoisseurs, and the general public. Artists could now go their own way and make their own choices.

In Mayan society (350 BCE–900 CE) artists had enjoyed high status because of their ability to record, and for most of its history the visual arts had played an essential role in supporting the status quo. Around 1840 the discovery of photography transformed the artist's position. Photography, the process of making pictures through the action of light, liberated the arts from the propagandist role that they had to play. There was now no need for painting to perform a task that a mechanical device could do far more effectively, and the camera took over as the principle means of recording, leaving artists free to criticize, comment, and give voice to their conscience and their creativity.

As a rule patrons and patronage systems did not encourage criticism of the existing social order. In societies
such as Soviet Russia (1917–1991), where the state was supreme, the arts were run by government organizations, and artistic freedom was curtailed in order to promote the new social order. Patronage and the status quo also played a critical role in freer, more democratic societies. In 1932 the Mexican artist Diego Rivera (1886–1957) was commissioned to paint a fresco for the Rockefeller Center in New York, one of the most ambitious urban designs of the century. Rivera, however, included a portrait of Vladimir Lenin, leading John D. Rockefeller (1839–1937) to cancel the commission and have the unfinished mural destroyed.

MATERIALISM
The advent of the Industrial Revolution had a profound impact on the decorative arts. The workshop gave way to the factory, while craftspersons and their individual skills succumbed to the machine and mass production. During the twentieth century, movements such as the Bauhaus (1919–1933) in Germany did their best to combat the effects of this trend. Combining the schools of art and craft, Bauhaus revived the creation of unique handmade objects. In an age driven by technology, the effect of these developments has been to place a premium on cost and time. This has made the possession of a handmade object even more desirable and even more exclusive than ever before.

As the expression of a living society, the nature of art was very closely tied to its material context. Economics often defined what artists could do, what they aspired to do, and the way in which their work was received. Centralization, urbanization, political stability, and control of resources were all key factors in this equation.

In Japan the growth of peace and prosperity during the Edo period (1603–1867 CE) fostered a vibrant cultural atmosphere. Literacy was widespread and the demand for art was so extensive that it could no longer be confined to a single group of patrons. This demand found its outlet in the affordable new medium of woodblock prints, which became the most popular art form of the day. Known as ukiyo-e (pictures of the floating world), they were filled with everyday subjects, reflecting the lives of the people who bought them. The two most famous series, Utagawa Hiroshige’s Fifty-three stages of the Tokaido (1833) and Katsushika Hokusai’s Thirty-six Views of Mount Fuji (c. 1826–1833), became the most popular sets of graphic art ever printed.

CHANGE
A striking characteristic of the visual arts is the way it often accompanies momentous changes in politics, economics, and science. The upheaval of the twentieth century led to revolutionary developments in art and culture. Photography had compelled artists to explore areas where the camera could not go, encouraging them to discard convention and experiment. Like the scientists who discovered penicillin and atomic power, and the inventors who created the telephone, the car, the airplane, and the computer, artists too committed themselves to a process of experimentation and discovery. As they did so, they questioned the nature of art itself.

Led by Paul Cézanne (1839–1906) and Vincent van Gogh (1853–1890), and then Picasso (1881–1973) and Georges Braque (1882–1963), artists deliberately abandoned the previous attitudes toward accurate representation. It was no longer important to represent what people see; humankind had gained such mastery over the appearance of reality that the only way forward lay in abstraction and nonrepresentation, the reality behind realism.

Visual art now aspired to create something more relevant, more meaningful, and more lasting than a copy of an object or a depiction of nature. In this cause new techniques and materials were adopted that resulted in the breakdown of the distinctions between art and everyday life. This search led to a new feeling for the arts of Africa, Australasia, and America, where art was charged with an almost magical power and had a living function in society.

“FOLK” PRACTICE AND “HIGH CULTURE”
In Nigeria, the Yoruba people still believe that a parent’s love can reach a dead child through the medium of art. Nigeria has one of the highest rates of twin births in the world; when a Yoruba twin dies, a wooden image, ere ibeji, is carved and kept in the house by the parents. A symbol of hope for the future, the image is bathed and fed in the hope that the dead twin will bring the parents good luck. Described as “folk” practice, many of these art forms were the product of a community with a shared view of the world and a shared way of life. Rooted in tradition and less open to change, this art did not question but merely reflected the values of its society.

“Folk” art or practice was distinct from what was called high culture, a term that implies a more rarified culture with a greater level of luxury and sophistication and perhaps a different kind of patronage. Fostered by the state and the ruling elite for its own enjoyment, it also served to display power and glory. Unlike folk culture, high culture was not static or tied to tradition. Based on knowledge, experience, and understanding, it was, like art during the Italian Renaissance, in a constant state of evolution. This capacity to grow made it capable of change, and it was able to explore new issues and to question and break barriers. As the product of a community, many forms of folk art did not have a single author. High culture in contrast was often the product of individual dis-
covery and endeavor. However this apparent difference may have been more the result of poor records and historiographic bias. What we do know is that the "high art" of Renaissance Italy was the result of individual genius, the work of such men as Leonardo da Vinci, Michelangelo (1475–1564), and Raphael (1483–1520), and as such its many forms were different and distinctive. The ceilings of the Sistine Chapel (1508–1512) in Rome, for example, would not have been painted in the same fashion by any artist other than Michelangelo.

FILM
The social impact of the visual arts is best summed up through the metaphor of film, the art of the motion picture. The youngest of the arts, the motion picture represents the logical development of everything that has come before. It was produced by recording a series of images with cameras and then showing them in rapid succession, thus giving an illusion of motion. Since the first commercial motion picture was made in 1898, the addition of sound and then color have made film arguably the most potent and popular art form of all. More so than other visual arts, it has an almost universal power of communication, possessing an ability to entertain, educate, enlighten, and inspire across countries and cultures.

Through film, culture has become truly global. Today the Coca-Cola logo is recognizable worldwide in numerous languages. The visual arts are no longer indigenous—the product of one particular culture or experience. A universal language has become or is in the process of becoming a universal experience.

VODOU
Based primarily on an amalgamation of spirit and ancestor cults and healing traditions brought by African slaves to the New World, and secondarily on African and European forms of folk Catholicism, Vodou (Voodoo) is the most popular religion among Haiti’s eight million citizens, most of whom are peasants. It is also practiced by a sizable minority of the two million Haitian immigrants (and a small number of converts of diverse ethnic backgrounds) in the Dominican Republic, the Bahamas, and North American cities like Miami, New York, and Montreal. The first Vodou practitioners in the United States were the African and Creole slaves of French plantation owners fleeing the violence of the Haitian Revolution (1791–1804), who settled mainly in New Orleans, where the religion remains part of the city’s religious fabric, sometimes practiced in concert with Hoodoo, a form of African American folk spirituality that is also based on ancient African traditions. Like any religion, Vodou is a system of symbols, beliefs, and practices that provides its adherents, whether in Haitian or American society, with a sense of meaning and purpose in life, a means of communing with the sacred, moral guidelines, a source of personal identity and group solidarity, and the courage to face life’s struggles.

Vodou emerged in the sixteenth century among enslaved Africans and their descendants in the western region of the Spanish Caribbean colony of Santo Domingo, which became the French colony of Saint-Domingue in 1697 and eventually the Republic of Haiti in 1804. Although possessing deep roots in West Africa and Central Africa, the religion is more correctly identified as African-derived or African-based rather than African, even if the term vodun (whose original meaning in the West African Fon language is “spiritual entity”) was reappropriated by practitioners of traditional African religions in West Africa in the twentieth century to designate their own religion. Like Santería and other major African-derived religions in the Americas, Vodou is an example of diffused monotheism, meaning that the sacred power of a single creator god, called Bondye (Good God) or Granmèt (Great Master), is diffused through a pantheon of divinities, which in Vodou are called lwa, and throughput nature. As such, the lwa are deeply enmeshed in nature, and each lwa is associated with some natural force or feature, like rivers, rainbows, the earth, and the sea.

From the beginning of the sixteenth century to the end of the eighteenth century, a total of some 800,000 enslaved Africans were brought to Santo Domingo/Saint-Domingue, the majority from the West African Fon and Central African Kongo ethnic groups. Numbering relatively few and facing opposition by slaveholders, Catholic missionaries managed little success in evangelizing slaves beyond administering the legally required sacrament of
baptism. The syncretism that would thereafter characterize Vodou thus resulted, as Catholic saints merged with African spirits, and crosses, holy water, and rosaries joined spiritual forces with amulets that slaves refashioned from African traditions, which proved remarkably resilient in the face of the unspeakable oppression of slavery.

Prior to the Haitian Revolution, a multiplicity of African religious traditions thus persevered in Saint-Domingue, whose sugar plantations made it Europe’s most lucrative colony. To speak of Vodou prior to the revolution is therefore somewhat anachronistic, as three of the religion’s cornerstones were not laid until the second half of the eighteenth century and the first half of the nineteenth century: (1) the unity of purpose of the Haitian Revolution, as exemplified by the powerful ceremony at Bwa Kayman in August 1791, led by a prototypical Vodou priest named Boukman Dutty, which is widely credited with having sparked the revolution; (2) the integration of essential African religious traditions that were being practiced during the colonial era in clandestine maroon settlements of escaped slaves in the island’s mountains and forests; and (3) the acceleration of the adoption of Catholic elements (especially hagiology) during the period of the “great schism” between Haiti and Rome from 1804 to 1860, when the Vatican refused to send Catholic priests to the young nation. After the schism, the Catholic Church, in alliance with the Haitian government, orchestrated several formal campaigns to suppress Vodou. These ultimately failed, however, and today the religion enjoys protection under the 1987 Haitian constitution, while in 2003 its baptisms and marriages gained legal recognition in Haiti.

Vodou has always been heterogeneous and decidedly decentralized, relying on neither the teachings of a founder, nor scripture, nor formal doctrine. In some parts of Haiti, for example, the religion is primarily characterized by ancestor veneration, and elsewhere by cults of spirits of West African origins, such as Ezili, the female lwa of love, sensualility, and feminine power, and Ogou, the male lwa of iron and all powers associated with metals. The Vodou pantheon is divided into two principle rites: the rada, whose lwa are “cool” and serene; and the petwo, whose lwa are “hot” and feisty. Many lwa have manifestations in each rite. Rada and petwo cults are supplemented for most practitioners by the veneration of their ancestors (zanset or lemb, “the dead”). Collectively, the lwa, zanset, and lemb, along with angels and Catholic saints, are identified simply as the “mysteries” (mistè).

Principal forms of communication and contact with Vodou’s mistè include prayer, praise, ablutions, offerings, spirit possession, drum and dance ceremonies, divination, and animal sacrifice. These rituals’ overarching aim is to ensure, establish, or reestablish harmony between practitioners and the mistè, or to protect practitioners from sorcery (wango). In the event of bad things happening, Vodouists consult with ritual specialists (female: manbo; male: oungan), who perform divination and orchestrate ceremonies (which most often take place either in temples (ounfò), family burial compounds, or public cemeteries) to provoke spirit possession and thereby enter into communication with the mistè in order to discover the cause of the underlying discord, disease, problem, or misfortune, and to determine and prescribe means of reestablishing harmony, healing, or achieving relevant solutions. Further drum ceremonies may be prescribed, while others are held according to a liturgical calendar derived from Catholicism.

Harmony between humans and the mistè and healing comprise Vodou’s raison d’être. In general, such harmony requires the ritual appeasement of the mistè, whether through splendidly artistic communal drum and dance ceremonies, animal sacrifice, or more frequent personal devotions such as praising and feeding the lwa. Healing, meanwhile, often involves herbalism and ritual baths. Leaves, water, song, dance, drums, blood, healing, and communion with the sacred are thus what Vodou is truly about. It is a dignified and complex religion of survival, resistance, and African roots that is quite the opposite of the ignorant and racist stereotypes that malign Vodou in Western imagination and media.

**VOLTAIRE**

1694–1778

François Marie Arouet was born in Paris in fall 1694 and died there in spring 1778. “Voltaire,” the name by which he
is most widely known today, was a pen name that François invented for himself, most likely in 1718. It is believed to be an anagram of the Latinized form—"Arovet le leune"—of his name "Arouet le jeune" ("Arouet the younger," because Voltaire's father, a notary, was also named François). Voltaire is the best known of the philosophes of the French Enlightenment, and there is an industry of modern scholarship on his life and thought, including hundreds of monographs, as well as the multiple-volume series Studies on Voltaire and the Eighteenth Century and the Complete Works of Voltaire, both published in Oxford by the Voltaire Foundation. A champion of religious tolerance and human reason, a "philosophical historian" and popularizer of social history, Voltaire was clearly one of the Age of Enlightenment's most influential contributors to what would become known as the social sciences.

Like many eighteenth-century men of letters, Voltaire wrote in several genres, in both prose and verse. When measured against the literary output of his enlightened contemporaries, Voltaire's staggering productivity—amounting to some 15 million words—stands out. Historians typically divide his life into five periods, or phases, based on his literary projects and his place of residence.

The first period of Voltaire's life is defined by his youth, his education at the hands of the Jesuits of the College of Louis-le-Grand, and the publication of his early poems and plays, including his first important publication, the tragic play Edipe (1715). It was also a period that saw the young Voltaire imprisoned in the Bastille for eleven months for writing libelous verse insulting to the king. In his youth, and throughout his long life, Voltaire was plagued by poor health, and he complained so frequently to his correspondents that modern scholars have identified hypochondria as one of his conditions.

The second stage of Voltaire's life was determined by his fleeing to England in spring 1726. His "exile" was occasioned by his having traded insults with the chevalier de Rohan. In England he mixed with Henry St. John, Viscount Bolingbroke (1678–1751), whose literary talents he admired and who introduced Voltaire to other writers, including Alexander Pope (1688–1744) and Jonathan Swift (1667–1745). Voltaire also read the works of the fathers of the English Enlightenment—Francis Bacon (1561–1626), John Locke (1632–1704), and Isaac Newton (1642–1727), whose burial at Westminster Abbey he attended. Voltaire's Lettres philosophiques sur les Anglais [Letters concerning the English nation] (1733) came out of this period, and he would long admire the English for what he perceived as their religious toleration, their defense of liberty, and their support of men of letters, such as Newton. It was also while in exile in England that Voltaire began to give serious attention to historical writings. While in England he published Essay Upon the Civil Wars of France (1727) and, more importantly, was probably working on the manuscripts that would become his Histoire de Charles XII [History of Charles XII] (1731) and Le Siècle de Louis XIV [The Century of Louis XIV] (1752), and also thinking about the history of the English constitution. Those activities continued after he returned to France in 1729.

The third period of Voltaire's life was the time of his residence at Cirey-en-Champagne, the château of the marquise du Châtelet (1706–1749), Voltaire's learned and witty mistress. Living there from 1733, Voltaire wrote poetry and plays, biblical criticism, popularizations of science such as Éléments de la philosophie de Newton [Elements of Newton's philosophy] (1738), and fiction, including Zadig (1747). These were also years in which he was working on Essai sur les moeurs et l'esprit des nations [Essay on the manners and spirit of nations] (1756), and frequently traveling throughout France, but also to Brussels. Voltaire's career was on the rise. In 1745 he was appointed historiographe du roi (historian to the king), largely owing to the support of Madame de Pompadour (1721–1764), and in 1746 he was elected to the French Academy.

With Madame du Châtelet's death in 1749, Voltaire accepted an invitation to take up residence at the court of Frederick II (1712–1786), the Great of Prussia, with whom Voltaire had corresponded from the mid-1730s. Frederick once claimed of Voltaire, "this great man alone was worth an entire Academy" (quoted in Aldridge 1975, p. 411). This fourth phase of Voltaire's life saw the publication of Voltaire's Le Siècle de Louis XIV [The Century of Louis XIV], (1752), an account that praised the French king for his support of literature and art, and also work on his Dictionnaire philosophique [Philosophical Dictionary] (1764). Voltaire also was involved in shady business deals, arousing Frederick's anger and helping to bring his stay in Prussia to an end only three years after it had begun. This was not the first of Voltaire's financial schemes, nor would it be the last. As Ben Ray Redman puts it in his introduction to The Portable Voltaire, Voltaire's "fingers began to itch whenever he thought there were soux to be made" (1949, p. 19).

The final stage of Voltaire's literary career was spent in Geneva, where Voltaire moved in 1755, and at Ferney, an estate he purchased in France near the French-Swiss border, in 1758. During these years he wrote The Lisbon Earthquake (1755) and contributed to the greatest of the French Enlightenment publications, the Encyclopédie edited by Denis Diderot (1731–1784) and Jean le Rond d'Alembert (1717–1783). Voltaire also published his Essai sur les moeurs (1756), worked on his History of the Russian Empire Under Peter the Great (1759, 1763), and published Candide (1759), which is perhaps the best known of his works. It was during his years at Ferney that Voltaire
penned his famous cry “écrasez l'infâme!” (“crush the infamy!”), the precise meaning of which historians continue to debate. It was also during this period that Voltaire became more vocal in his deism and more involved in several public events, including the Calas affair, in which he used his pen to defend the reputation of Jean Calas, a Huguenot who was tortured and executed in 1762. In 1764 Voltaire published *Dictionnaire philosophique*. His literary reputation was growing in the 1760s and 1770s, and the aging Voltaire was often visited by guests from around the world. In winter 1778, when Voltaire was eighty-four, his play *Irène* (1776) was celebrated in Paris. He died soon afterwards, the most famous man of letters of the Age of Enlightenment.

Voltaire's social and political thought is found throughout his satires, pamphlets, and voluminous correspondence, but it is his historical writings that contain some of his most important contributions to the social sciences. As an historian, Voltaire was forward looking, and he saw himself to be presenting history in a new way. Writing with a critical spirit similar to those of Pierre Bayle (1647–1706), François Fénelon (1651–1715), Bernard le Bovier de Fontenelle (1657–1757), and Henri de Bougainvilliers (1658–1722), Voltaire was less credulous than the humanist historians of the seventeenth century, and it is largely for that reason that he is considered by some to be the forerunner of modern historiography. He aimed to incorporate more sources and a greater variety of sources than did most of his contemporaries, even though some, such as Edward Gibbon (1737–1794), thought Voltaire did not go far enough in this regard. In his efforts to expand the subject matter of history in the direction of social and cultural history, Voltaire shared a common concern with other great Enlightenment historians, such as David Hume (1711–1776). In his “An Essay on Universal History” (1756), for example, Voltaire dispensed with Christian structure to tell the story of the rise and fall of civilizations, beginning with the ancient Chinese and also including America. In that grand narrative and in other historical works Voltaire showed little concern with military events and the rule of princes, but he found a primary role for economics. As J. H. Brumfitt summarizes in *Voltaire: Historian*, “more than his predecessors, and more than many of his contemporaries, who are often involved in abstract political theorizing, he succeeds in giving to economic developments a place in the narrative of history not too far removed from that which they occupy today” (1958, p. 70). Again in a notably modern way, Voltaire aimed to go beyond history as the recital of disparate and unconnected events. In the Siecle, for example, he attempted to integrate economics, politics, and the arts and sciences, and to present all of that in a unified whole. Part of Voltaire’s appeal as an historian, then and now, was his realist’s approach to change over time. As the historian Peter Gay put it in *Voltaire’s Politics: The Poet as

**Realist**, Voltaire was “a practical hard-headed political man” (1959, p. xi). Near the core of Voltaire’s historical thought, as with his philosophical writing, was an unrelenting attempt to appeal to reason at the expense of fable, myth, superstition, and religion. That tendency, more than anything else, explains why Voltaire was, as Theodore Besterman summed up in *Voltaire*, “the most famous, the best loved and the most fanatically hated man in Europe” (1969, p. 528).

**VOLUNTARY UNEMPLOYMENT**

In principle, a voluntarily unemployed person is a jobless worker refusing an available vacancy for which the wage is lower than a certain threshold known in the literature as
reservation wage. John Maynard Keynes, in his *The General Theory of Employment, Interest, and Money* (1936), when describing the classical view of unemployment, introduces the notion of voluntary unemployment as "a refusal or inability of a unit of labor [...] to accept a reward corresponding to the value of the product attributable to its marginal productivity." According to this definition, frictional unemployment due to job searching would be voluntary, while unemployment determined by demand factors would be involuntary.

Robert E. Lucas Jr. criticizes this view, since "there is an involuntary element in all unemployment, in the sense that no one chooses bad luck over good; there is also a voluntary element in all unemployment, in the sense that however miserable one's current work options, one can always choose to accept them" ([1978] 1981). Unemployment should then always be viewed as voluntary, as alternative activities are always available in the economy. This interpretation is consistent with Ludwig von Mises that states, "Unemployment in the unhampered market is always voluntary. In the eyes of the unemployed man, unemployment is the minor of two evils between which he has to choose" (1949).

However, the question of voluntary versus involuntary unemployment should not be overemphasized. Indeed, for the majority of workers there is often a chance of being employed at a certain wage level. Nevertheless, even if a worker would refuse such a job offer, this does not seem to be enough to classify him as merely voluntarily unemployed.

Richard Layard, Stephen Nickell, and Richard Jackman (2005) make the example of the unskilled workers, for whom the number of well-paid jobs with good working conditions is far below the number of potential applicants. Therefore, the majority of the unskilled turn to jobs that pay less and are in general of worse quality. These jobs are easier to find and in some cases offer the possibility of immediate employment.

The labor market can then be divided into two sectors. One is identified as primary, where the best jobs are available, and the other is called secondary, where jobs are on average lower pay and of lower quality. In the secondary sector the labor market is said to clear, as vacancies are filled very quickly, the skills needed for the jobs are modest, and the wages are too low to appeal to a large number of applicants. In the primary sector the labor market does not clear, and job rationing results. Some of the workers excluded from the primary sector are subsequently employed in the secondary sector while others remain unemployed, according to the reservation wage of each individual.

Assuming that total labor force is equal to L and that all workers are willing to be employed in the primary sector, we can assume a negatively sloped labor-demand curve in the primary sector DD1. The latter identifies the primary sector employment N1 corresponding to the real wage W1/P1 resulting from union bargaining or firms' efficiency-wage policies. The number of workers available for secondary-sector jobs is then L – N1. The positively sloped labor-supply curve in the secondary sector, SS2, is determined by the reservation wages of these workers and is affected by the characteristics of the unemployment benefit system. The negatively sloped labor-demand curve in the secondary sector, DD2, illustrates the demand of secondary-sector labor for any given level of real wage in that sector W2/P2. The market-clearing equilibrium is then reached when SS2 = DD2 and the employment level in the secondary sector N2 is determined. The resulting unemployment level is then U = L – N1 – N2.

The nature of unemployment U is questionable. From one point of view, the workers in U are voluntarily unemployed because they are not willing to work in the secondary sector for a real wage that is below a certain threshold given by their reservation wage. However, they are also involuntarily unemployed because they are willing to work in the primary sector at the prevailing real wage but are not able to do so.

In a dynamic setting, the relative importance of the primary and the secondary sector varies according to aggregate as well as idiosyncratic shocks. Workers move within the three states (primary sector, secondary, and unemployed). Some of them will search for primary-sector jobs while unemployed, while others will become employed in the secondary sector.

It is the primary-sector real wage, which is the result of union bargaining or wage-efficiency policies, that will determine primary-sector employment, the crucial element in this representation. The entity and duration of unemployment will result from the general equilibrium of the economy.

VOLUNTEER PROGRAMS

According to the Corporation for National and Community Service (CNCS), 65.4 million Americans reported that they volunteered in 2005 (the latest year for which data are available), almost 30 percent (28.8 percent) of the U.S. population (CNCS 2006). In 2000 the substantial volume of time volunteered by Americans was the equivalent of 9.1 million full-time employees (based on 1,700 hours per year per employee). The total assigned dollar value of volunteer time in that year was 239.2 billion dollars, which grew to an estimated 280 billion dollars in 2005 (Independent Sector 2001).

Volunteering is, of course, not limited to the United States; although variations exist across countries (Salamon and Sokolowski 2001), volunteering has emerged as “an international phenomenon” (Anheir and Salamon 1999). According to Salamon and Sokolowski’s research on volunteering in twenty-four countries (2001), volunteering constitutes 2.5 percent of non-agricultural employment on average. In their study, this percentage ranged from a low of 0.2 percent in Mexico to a high of 8.0 percent in Sweden.

In the past, volunteering was mainly regarded as work or activities contributed to private charitable or religious organizations. However, volunteers have become a crucial resource for various types of organizations not only in the nonprofit sector but also in the public sector. As an example, the 1992, 1990, and 1988 Gallup surveys on volunteering in the United States show that a significant portion of volunteer efforts went to government organizations (Brudney 1999).

Having such a large amount of time directed to volunteer work does not assure that desirable results are attained for host organizations or volunteers, or for the targets of their well-intentioned efforts. Different issues may arise depending on the types of volunteering activities or on the social and organizational context, and even the nation where volunteering occurs. A 2004 survey on volunteering policies and partnerships in the European Union, for example, suggests that volunteer regulations, policies, and laws differ substantially cross-nationally (Van Hal, Meij, and Steenbergen 2004).

Attaining beneficial outcomes from volunteer involvement for participants, clients, organizations, and the community requires a programmatic structure. Below we explain how to provide this structure for volunteer programs. To do so, we elaborate and extend a model proposed by Young-joo Lee and Jeffrey L. Brudney (2006), based on the essential challenges that all volunteer programs must meet.

CHALLENGES CONFRONTING VOLUNTEER PROGRAMS

A volunteer program is a systematic effort to involve volunteers in the work, outputs, and outcomes of an organization. Several authors have proposed models to guide volunteer programs (Boyce 1971; Dolan 1969; Kwarteng et al 1988; Lenihan and Jackson 1984; Penrod 1991; Vineyard 1984). A review of these models shows that they are quite similar, being grounded in a set of core functions that these programs typically perform, such as selection, orientation, and job design. Rather than considering the activities conducted, the challenge model focuses on the goals that must be met to achieve successful performance with volunteers. Although research on the validity of volunteer program design models is scant, a study based on a heterogeneous sample of government volunteer programs suggests that various elements of the challenge model are related empirically to the perceived effectiveness of these programs (Hager and Brudney 2004; Brudney 1999).

Lee and Brudney’s A New Challenge Model of a Volunteer Program (2006), developed originally to guide school volunteer programs, can be extended to the design of volunteer programs in general. These researchers outline six principal challenges that confront volunteer programs:

1. recruiting citizens for volunteer service;
2. engaging the community in the volunteer program;
3. gaining acceptance from organizational members;
4. maintaining accountability, to ensure that volunteers adhere to the values and goals of the organization;
5. managing the program effectively through structural design;
6. evaluating the program’s processes and results.

Figure 1 presents the challenge model of a volunteer program. The article discusses, in turn, each challenge a volunteer program must meet.

Recruiting Citizens Perhaps the greatest challenge to an effective volunteer program is attracting people willing and able to donate their time and expertise. Volunteerism expert Susan Ellis (1996b, pp. 5–6) cautions that “recruitment is not the first step” in a program; a volunteer program must have a clear purpose or goal and meaningful work for volunteers to carry out. Yet, without sufficient volunteers, a program cannot be sustained.

It is important to provide potential volunteers with incentives to participate in the program. A powerful motivation for most volunteers is the idea that their efforts will provide a benefit to the recipients of volunteer service, which in turn will bring them a sense of fulfillment. Most
Volunteer Programs

Volunteers say that they volunteer to “help other people” or “do something useful” (Brudney 2005, p. 329). Thus, an emphasis on the benefits of a volunteering program would likely prove an effective volunteer recruitment strategy. Another incentive is the benefit to volunteers themselves. Research has shown that there are positive effects of volunteering for volunteers, such as improved health, increased occupational skills, greater networking and social support, and enhanced self-confidence and self-esteem (Wilson and Musick 1999).

The most effective recruitment strategy is to ask people to volunteer. Research findings show that people volunteer far more frequently when they are asked to do so. For instance, the Independent Sector reported that 71.3 percent of the people who volunteered had been asked to volunteer, compared to just 28.7 percent of the non-volunteers (Independent Sector 2002, p. 68). To recruit volunteers, experts recommend targeting groups or organizations with a membership of potential volunteers. For instance, recruitment efforts can be made in workplaces, churches, and synagogues, and directed at neighborhood groups, civic associations, and other institutions in the community (Ellis 1996b).

Engaging the Community As more organizations, including nonprofit, government, and even for-profit, have implemented volunteer programs, an evolution has occurred in the traditional population of volunteers (Smith 1994). Volunteers are no longer predominantly middle-aged, middle-class white women. Instead, they embrace a much wider segment of the community, including males, youth, seniors, people of color, and so forth (CNCS 2006).

A significant consequence of the growth in the number of volunteer programs and an increasingly diverse volunteer pool is that host organizations must compete for volunteers with other nonprofit, government, and corporate volunteer programs. In order to attract volunteers, volunteer programs must emphasize the contribution or impact of a program, its uniqueness, and its connection to the community. Competition also requires volunteer programs to network with other organizations to gain resources and support, such as funding, legitimacy, volunteer opportunities, in-kind contributions, and publicity.

Gaining Acceptance As Brudney (1994) points out, satisfying an organization’s internal constituencies is a prerequisite to setting up an effective volunteer program. Prior to establishing a program, proponents must gain acceptance from, among others, paid staff, board members, clients, and affiliated organizations, such as labor unions and professional associations (if they exist). Without the commitment and support of these stakeholders, the success of a volunteer program is questionable. The likelihood of gaining acceptance increases with the benefits the program may offer, not only to the clients of the program, but also to internal constituencies, volunteers, and the larger community. These benefits can be substantial and include: more attention to clients, greater opportunity for innovation, higher levels of service, increased fund-raising capability, enhanced cost-effectiveness, more satisfying and professional work opportunities, and greater community knowledge, feedback, and involvement (Brudney 2005).

Maintaining Accountability A host organization must make sure volunteers understand the work to be done and the authorized organizational methods and procedures for carrying it out. Accountability makes it possible to recognize and reinforce superior performance by volunteers and, correspondingly, to identify and make changes where performance is inferior or lacking.

In order to ensure accountability, organizational leadership should appoint or hire a volunteer administrator (or coordinator or director) responsible for the overall management and participation of volunteers (Brudney 1996; Ellis 1996, p. 55). The position is usually part-time or constitutes a portion of the duties of a full-time position. Studies find that organizational support for this position is strongly associated with the success of a program (Urban Institute 2004).

Establishing accountability for the volunteer program also includes having a program structure that organizes and integrates the volunteer effort. The program should have job descriptions for volunteer administrators as well.
as for the volunteer positions to be filled (Brudney 1996). In the United States, the Volunteer Protection Act of 1997 (Public Law PL105–119) strongly encourages organizations to have job descriptions for their volunteers. In addition, written policies and procedures should be on file that specify the rules and regulations concerning volunteer involvement, including the rights and responsibilities of volunteers as well as appropriate behavior and norms on the job (for example, confidentiality, reliability, and attire).

Managing the Program As several authors have noted, managing volunteers is not the same as managing employees (Farmer and Fedor 1999; McCurley and Lynch 2006). For example, volunteers are far less dependent on the organization than paid employees and contribute far fewer hours. Given these differences, the volunteer administrator assumes a critical role in the program. Ideally, volunteer administrators should have the following qualifications (Ellis 1996b, p. 60):

1. background in volunteerism or volunteer administration;
2. ability and/or experience in management;
3. proficiency in job design and analysis;
4. skills in leadership;
5. understanding of the needs of those to be assisted through volunteer effort;
6. familiarity with community resources;
7. interest in outreach to the community.

The volunteer administrator’s job typically includes recruiting, screening, orienting, training, placing, supervising, evaluating, and recognizing volunteers. This official also has to attend to risk management (Graff 2003). Liability with respect to volunteer programs applies to situations in which a volunteer is harmed while performing his or her duties, as well as when a third party is harmed by a volunteer (Lake 1997). Given the distinctive duties of volunteer administrators, the literature endorses specialized training and preparation for the volunteer administrator position (Ellis 1996b; McCurley and Lynch 2006).

Evaluating the Program Evaluation provides the ultimate justification for a volunteer program. Brudney (1996, p. 201) defines evaluation as “collecting systematic information on the processes and results of the volunteer program and applying these data toward program assessment and, hopefully, program improvement.” To evaluate the effectiveness of volunteer involvement, Brudney recommends focusing on three target audiences: the clients or intended beneficiaries of the volunteer program, internal constituencies, and the volunteers themselves. A variety of methods exist for evaluation of volunteer programs (Gaskin 2003; Goulborne and Embuldeniya 2002).

Of all the challenges, evaluation apparently receives the lowest priority in volunteer programs (Brudney 1999), perhaps as a consequence of the donated nature of volunteer effort. Organizations may be wary of questioning the involvement or effectiveness of citizen volunteers. Nevertheless, just as with any systematic activity, organizations should assess volunteer programs and learn from the results. As Figure 1 shows, the information gained from evaluation should be fed back to the organization and used to improve the volunteer program.

CONCLUSION
A volunteer program requires an investment on the part of an organization, internal constituencies, and volunteers. Some may ask whether this investment is worth the effort. Indeed it is: Volunteerism benefits all parties involved. Benefits to clients include receiving needed services and the feeling that someone is interested in and cares about them. Benefits to organizations include increasing cost-effectiveness, expanding programs, and raising service quality. Benefits to communities include enhanced civic participation and awareness.

Research has shown that, with respect to the monetary return on investment, volunteer programs routinely yield more in dollar value than organizations expend on them (Gaskin 2003). For clients, volunteers, and communities, the social and psychic benefits are likely to be far greater.

VOLUNTEERISM

Volunteerism refers to a broad range of activities that benefit another person, group, or cause and that are carried out by individuals by their own choice and without pay. Individuals engaged in volunteerism are referred to as volunteers. Examples of volunteerism include serving on the board of a museum, organizing a protest meeting against environmental pollution, preparing food in a soup kitchen, caring for the elderly in a nursing home, looking after pets or mail for a neighbor, and the donation of blood at a blood center. However, also more controversial activities like distributing flyers for an extremist political party and providing shelter to illegal immigrants may qualify as examples of volunteerism.

A common distinction is made between formal and informal volunteerism. Formal volunteerism is carried out in an organization, usually a nonprofit organization. Informal volunteerism is not carried out in an organization and usually benefits specific individuals or groups with whom the volunteer has personal connections. Informal volunteerism is also called social support or helping behavior. Informal volunteerism that benefits colleagues or one’s employer is called organizational citizenship behavior.

In sociology and political science volunteerism is considered a form of civic engagement and an expression of cohesion or social capital in society (Putnam 2000). Formal volunteerism has received more attention in these disciplines than informal volunteerism, although the two are related empirically (Wilson and Musick 1997).
focus on formal volunteerism is apparent in the frequent measurement of engagement in voluntary associations in general household surveys. These surveys contain lists of types of organizations, for each of which the respondent answers to what extent he or she is engaged in the organization (not engaged, passive member, active member, volunteer). In some household surveys respondents report the frequency of informal helping behaviors. Informal volunteerism is commonly measured in questionnaires on social support networks. Respondents indicate whether they have people (“alters”) available to them with whom they discuss important matters (emotional support) or who can assist them in practical matters like small repairs (practical support).

Volunteerism is more common among married persons, whites, the middle-aged and elderly, the higher educated, more frequent church attendees, rural residents, children of volunteers, and extraverted persons (Bekkers 2005, 2007; Penner et al. 2005; Putnam 2000; Wilson 2000). Differences between whites and blacks differ from study to study (contrasting findings in Wilson and Musick 1997 and Carson 1987). Among other things, volunteerism is more common among the higher educated because they have more civic skills, more knowledge, and a stronger feeling of efficacy (Brady et al. 1995; Nie et al. 1996). Individuals with more civic skills and knowledge are more able to understand arguments, to express their views, and to convince others. These are useful qualities that lower the cost and increase the expected benefit of volunteerism. Individuals with a stronger feeling of efficacy are more likely to think their volunteerism makes a difference for the beneficiary of their volunteerism, which increases its expected benefit. Formal volunteerism in turn enhances civic skills, knowledge, and self-efficacy. Beyond paid work, voluntary associations are an important context in which people gain experience in organizing meetings, learn to understand others, and gain confidence in their abilities.

Volunteerism is also linked with a variety of other benefits. Volunteers are known to live longer and to be healthier in old age than nonvolunteers. In addition volunteerism contributes to mental health and may contribute to success in paid labor in the long run (Penner et al. 2005; Wilson and Musick 2000). At the macro level voluntary associations strengthen civil society and democracy (Putnam 2000).

Because of these benefits, schools increasingly include service learning and community service programs in their curricula. Completing a service learning program, which itself is usually not a form of volunteerism because it is obligatory, may promote civic skills and volunteerism in the future, depending on several characteristics of the program. More beneficial programs have a moderate level of freedom for pupils in selecting service activities, require a higher level of reflection from pupils, and are supervised by more enthusiastic teachers (Metz and Youniss 2005). Voluntary programs do not have more beneficial effects than required programs (Schmidt et al. 2006). Voluntary programs draw an audience that consists mostly of young people with a social background that facilitates volunteerism: parents volunteer themselves, are religious, and have higher socioeconomic status (Metz and Youniss 2005). Given that required service learning programs also have beneficial effects among youths from less-favorable backgrounds and perhaps even more so than among youths from advantageous backgrounds, required service learning programs may reduce social inequality in volunteerism and civic engagement in the long run.

VON NEUMANN, JOHN
1903–1957

John von Neumann (born December 28, 1903 in Hungary, died February 8, 1957 in Washington, D.C.) was a versatile scholar whose path-breaking ideas have enriched various disciplines. In social sciences his contributions to game theory, economic growth, and consumers’ choice are of special importance.

Von Neumann’s talents showed up early, and outstanding mathematicians tutored him individually. In 1923 he entered MSc chemistry studies in Zürich and at the same time studied for a doctoral degree in mathematics in Budapest. In 1926 and 1927, as an assistant to David Hilbert in Göttingen, he laid down the axiomatic foundations of quantum mechanics. His reputation grew rapidly, and he was invited to several universities. He visited Princeton University first in 1929 and became a professor of mathematics at its Institute for Advanced Study in 1933. He became a leading expert on shock and detonation waves, which became significant during World War II (1939–1945), when von Neumann became involved in important projects such as the Manhattan Project. It was mainly the complex nonlinear problems that emerged in these projects that made him realize the importance of computers, and he made key contributions to formulating the basic principles of computer science.

Von Neumann made major scientific contributions to the social sciences as well. As always, he was interested in comprehensive structures, and focused on the core problems in the field. He was the first to prove the existence of equilibrium for two-person zero-sum games in 1928, based on his famous minimax theorem. Using a similar mathematical structure he formulated a multisectoral model of balanced economic growth (first presented in 1932), which was a brilliant mathematical synthesis of some classical ideas concerning the production and price proportions of economic equilibrium. He was the first to employ a fixed-point theorem in the proof of existence of competitive equilibrium, on the one hand, and an explicit duality approach, recognizing the symmetry of the conditions that characterize the choice of optimal activities and the equilibrium price system sustaining it under the conditions of a competitive equilibrium, on the other. His model allows for different theoretical interpretations (classical, Marxist, neoclassical, etc.) indicating its general nature.

Although his model was a prototype of the highly abstract models used in modern economics, he cautioned often against the potential deterioration of such an approach into intellectual games. He saw this danger threatening not only the development of economics but also mathematics itself. He repeatedly criticized economists for not using more appropriate mathematics, and he emphasized the need for more comprehensive tools than those borrowed from classical physics.

Von Neumann set an excellent example for such a novel approach in his work with Oskar Morgenstern on game theory. In their book, *Theory of Games and Economic Behavior* (1944), they laid down the foundations of modern game theory and initiated a new discipline almost from scratch. It was in this connection that they developed the axiomatic theory of expected utility, which states that under certain conditions the preferences of a rational individual can be represented by a function of the expected utility form. The use of the von Neumann–Morgenstern expected utility function became universal in economics because it is analytically very convenient and its normative character may provide a valuable guide to rational actions. Although he darted only briefly into its domain, von Neumann’s tremendous influence on the development of modern economics has been widely acknowledged.

VOTE, ALTERNATIVE

The alternative vote is an electoral method wherein voters rank candidates, and the winner is determined by a sequential count in which the weakest candidate is repeatedly eliminated until one candidate has secured a major-
ity of the vote. Electoral-law terminology is unfortunately nonuniform, but the alternative vote can be regarded as a special case of the “single-transferable vote” or the “preferential vote,” with the conditions that only one candidate is elected per district, and election requires an absolute majority. Most real-world examples of this system come from Australia, but it has also seen use elsewhere.

An example from the 1952 election in the Canadian province of British Columbia (Table 1) clarifies how it works.

Voters could rank as many of the four candidates as they liked, and the “first count” column shows how many placed each candidate in first place. None of the four had the necessary majority (5,771) immediately, so the last-place candidate, the Progressive Conservative (P.C.), was eliminated. The second-count “transfer” column shows how the 1,690 ballots on which Wright was ranked first were then redistributed: 169 of those ballots had no further rankings, and were thus discarded; 937 of them had Turnbull ranked second; and so on. Following elimination of the candidate from the Co-operative Commonwealth Federation (C.C.F), the Social Credit (S.C.) candidate, Robert Sommers, ultimately won the seat on the third count.

Advocates of the alternative vote often stress that it tends to be more proportional than simple plurality election, wherein voters pick one preferred candidate and whichever candidate wins the most votes wins the seat. In other words, the proportions of votes and seats won by the parties are usually more nearly equal under the alternative vote system. Again, British Columbia illustrates. The 1952 and 1953 elections were held using the alternative vote (“vote” in Table 2 refers to first count), whereas later elections awarded seats by plurality.

Unlike proportional-representation electoral rules, which ensure very close equality between seat and vote shares, the alternative vote merely tends not to exaggerate the support for large parties when turning votes into seats as drastically as does plurality.

One criticism of the alternative vote is that getting higher rankings can actually cause a candidate to lose a seat. The example in Table 3, devised by Steven Brams and Peter Fishburn, demonstrates this surprising trait. Candidates A, B, C, and D are competing for the seat, and the voters fall into four types, according to their preference rankings.

The outcome is a win by candidate A, as shown in Table 4 (since all voters ranked all candidates, exhausted ballots play no role).

Now suppose that the Type-IV voters move A up from last place to first place, so that their rank ordering is A, D, C, B. If all other voters remain the same, the outcome is now shown in Table 5.
Candidate B wins. Candidate A did worse (losing, not winning) because some voters gave him a higher ranking. If voters recognize the possibility of outcomes like this, they have incentives to misrepresent their preferences. Surprisingly, however, all electoral systems are vulnerable to such strategic voting.

VOTING
Voting is the central act of democracy, the method by which citizens influence the policy of the state by holding the leaders who represent them accountable for their decisions. It is also the means by which elected leaders make decisions in legislatures, and it is used outside government in businesses, civic organizations, social groups, and families in every modern society. This entry focuses on voting for elected offices because that type of voting defines democracy.

WHY DO PEOPLE VOTE?
Does voting make a difference? Almost all political scientists agree that political leaders in democracies respond to voters in a way that leaders in undemocratic, or “authoritarian,” countries do not. Because representatives in democracies are accountable to voters, they are much more likely to do things that benefit large sectors of society (rather than their friends and families)—for example, providing public goods such as infrastructure, public safety, and education and adhering to the rule of law rather than relying on arbitrary decisions about who should have access to government resources.

Political leaders in authoritarian countries are not entirely unaccountable to ordinary citizens. They must provide at least minimal government services or they eventually will face revolt or at the very least citizens who express their displeasure by cheating the system, refusing to do what they are told when no one is watching, and engaging in other subtle forms of resistance. When politicians must compete against one another for votes, the degree of accountability to ordinary citizens is much higher, much as merchants in a competitive marketplace offer better prices and higher quality than does a seller with a monopoly.

Though voting is clearly important for society as a whole, the question of why individuals vote is more problematic: One vote among thousands seems to matter very little. This is a classic example of a collective action problem in which many people working together can produce something that benefits them all but any individual’s contribution adds little to the whole and its absence will not be missed; as a result any particular person has little incentive to contribute. For the individual, then, voting appears to be irrational because one vote would not change the outcome but voters and nonvoters alike share the results.

In some political systems politicians solve this problem by trading money or favors to the citizens who are willing to vote for them, a practice known as patronage. Although this strategy motivates people to vote, most scholars believe it compromises the nature of democracy. Another strategy is to instill civic pride and responsibility in voters so that they see voting as an important part of their role in the community. This strategy also can work for dedicated groups within a larger society, such as labor unions, which often expend a great deal of effort encouraging their members to vote. Some societies even adopt compulsory voting, forcing citizens who do not vote to pay fines. Also, whatever people perceive the benefits of voting to be, they are more likely to vote if casting a vote is easy to do.

In part because politicians, parties, and governments in different countries have adopted different strategies to encourage citizens to vote and in part because of differences in political cultures among countries, levels of voter turnout vary dramatically from one country to the next and often change over time. The United States, for example, had lower voter turnout rates throughout the twentieth century than those of most other rich democracies, and that pattern continued into the twenty-first century; however, turnout rates in most Western European countries declined after the 1970s, whereas U.S. rates remained stable over that period among eligible voters (though the presence of increasing numbers of noncitizens and disenfranchised convicts in the population created the appearance of a decline in U.S. turnouts). Especially low turnouts can call the legitimacy of elections into question because actual voters may not be representative of society as whole. Because poorer and less educated voters are less likely to turn out than are their fellow citizens, low turnouts harm parties that draw more support from those voters.

THE HISTORY OF VOTING
Voting dates at least from ancient times, with well-known examples including the Greek city-state of Athens, the republic of Rome, and the direct ancestors of modern leg-
islatures: the assemblies, or parliaments, of medieval Europe. In all those cases the only people allowed to vote were males who held important social positions (members of the nobility or clergy) or owned a certain amount of property; the vast majority of adults, including women, could not vote.

The fight to create democratic government in Europe was therefore as much a fight over who got to vote as it was a fight over whether the king or the parliament would be supreme. Disenfranchised groups placed the right to vote at the forefront of their fights for equality both for its symbolic importance as the mark of full citizenship and because it gave them the political power to pursue other goals. During the nineteenth and early twentieth centuries pressure from the lower classes, often organized by labor unions, resulted in the lowering of property qualifications until finally universal male suffrage became the norm throughout Europe and the Americas. Beginning in the late nineteenth century, those countries witnessed a push to give women the right to vote, and by the late twentieth century nearly every country in the world had adopted universal suffrage.

As a result the right to vote ceased to be the true measure of democracy because authoritarians found ways to give people the right to vote without turning over real political power. One example was the American South, where the United States freed black slaves and gave them the right to vote after the Civil War ended in 1865. Strict requirements such as literacy tests and poll taxes (requirements usually waived for poor, uneducated whites) prevented blacks from voting until those measures were overturned by the Voting Rights Act of 1965. In the first decade of the twenty-first century laws in many U.S. states that prevented convicts and even ex-convicts from voting continued to affect blacks disproportionately.

A far more popular strategy has been to ban all political parties other than the ruling party or to make it difficult for other parties to organize and campaign. A more subtle method to reduce the power of the vote is the practice of patronage, or “machine” politics, in which politicians trade money or favors for votes; this practice was easier to implement before the secret ballot was adopted in most countries in the late nineteenth century, but politicians have devised numerous ways to reward loyalty and punish disloyalty even when votes are secret. Those politicians are accountable to voters, but there is little political competition; the politicians are political monopolists and are less responsive to voters than are politicians in a competitive system.

In a society with deep ethnic, racial, or national divisions, the members of each ethnic group typically vote only for politicians and parties of their own group. Some scholars consider ethnic solidarity in voting a reasonable exercise in self-determination, especially when minority groups attempt to oppose an oppressive majority. However, other scholars argue that not only does this situation produce a monopolistic relationship between leaders and voters that encourages patronage, but when the majority as well as the minority votes along ethnic lines, the majority wins every election and the minority has little reason to participate in the political system, a situation that leads to conflict that may turn violent.

In some countries legislators represent districts with unequal numbers of constituents, giving voters in smaller districts more power. This normally happens for historical reasons (for example, when people move from rural districts to urban ones), but parties with strong support in the smaller districts typically oppose any changes. In addition, officeholders sometimes “gerrymander” district boundaries, drawing them so that even if districts are equal in size, they tend to favor the election of one party or of incumbents in general.

Even when everyone has an equal right to vote and elections are competitive, casting votes may be difficult. In the United States citizens must register to vote before an election, and this requires extra time and effort. By contrast, in many countries all adult citizens are automatically eligible to vote. The actual act of voting may be problematic as well, especially when elections are held on working days or transportation to the polls is difficult to obtain. Low levels of education also may pose a barrier because people who cannot read or understand complex political concepts may have little ability to choose candidates wisely and little interest in doing so. Negative campaign ads and bad weather discourage many voters, strengthening the role of the most dedicated (and typically most extreme). Some scholars have argued that voters can grow apathetic as a result of “election fatigue” resulting from multiple elections within a specific period or multiple races at each election. The United States, with its many state and local as well as national elections, provides a clear example of this problem. Because many barriers to voting disproportionately affect the poor and less educated, efforts to raise or lower those barriers often become the objects of political dispute, with parties that draw more votes from the affected groups arguing for lower barriers.

At the other end of the spectrum the ability to provide campaign contributions or mobilize voters may give rich individuals and well-organized groups a more powerful voice in elections. Though all countries have restrictions on these sorts of activities, it seems unlikely that those advantages can be eliminated completely, and some scholars argue that private funding of political causes is necessary to provide true opposition to the government in power.
ELECTORAL SYSTEMS

Except in a few small communities where citizens vote directly on every issue, voters elect representatives to a legislature and, in some countries, executive offices such as the presidency. The first traditional method of electing legislatures is single-member districts (SMDs), in which the candidate who receives the most votes is elected; in countries with presidential systems presidents usually are elected this way. SMDs tend to produce two-party systems because parties with similar ideologies are more likely to win in each district by uniting. This system encourages direct accountability of representatives to a set of constituents, and this can make individual politicians more important than parties; however, the presence of only two parties gives voters a clear choice.

The other traditional form of voting is proportional representation (PR), in which each district elects many representatives and people vote for parties rather than individual candidates, with each party receiving a share of seats in the legislature proportional to its vote (in a rare variant known as the single transferable vote system [STV] voters actually vote for individual candidates, listing them in order of preference, but the system nonetheless produces proportional representation of parties). PR produces multiparty systems, requiring parties to form coalitions to rule. Because people vote for parties in PR systems, parties are usually strong and have clear platforms. In addition, voters never fear that their votes will be wasted as a result of their living in districts where their parties are always in the minority.

Because of this, it is thought that PR systems favor minorities whose members are spread evenly across geographical districts: In an SMD system a minority that is a minority in every district will win no seats, whereas in a PR system it will win a percentage equal to its share of the population. In practice, however, a minority that would lose every seat in an SMD system would end up with a minority in a PR system and thus, despite having symbolically important seats in the legislature, would be unable to pass legislation unless it could take part in a coalition (and a coalition would work equally well to gain a majority in SMDs), though in most legislatures a sizable minority may be able to block certain legislation or at least prevent constitutional amendments.

This concern applies most clearly when an electoral minority is a permanent one, as is the case in an ethnically divided country. In a competitive democracy, whether SMD or PR, the greatest barrier to “tyranny of the majority” is that no majority is permanent and therefore the members of the current majority have incentives both to treat potential future allies in the current minority well and to institutionalize respect for the minority because they themselves will be in the minority eventually.

Some countries have adopted other systems in an attempt to combine the best features of SMDs and PR. An open-list PR system allows voters to choose specific candidates within each party. An SMD system with a primary election allows voters to choose among competing candidates with similar ideologies in the primary. This narrows the choice in the general election to a clear one between two (or at most a few) candidates; holding a runoff if no candidate wins a majority in an election works in much the same way. Multiple voting allows each voter to vote for several different candidates in one district; each voter receives a number of votes equal to the number of offices to be filled, with all candidates competing against one another. An SMD system with alternative voting lets voters rank candidates in order of preference, allowing someone to support a first-choice party without hurting the chances of a second-choice party to win out over parties the voter dislikes; like STV, this is a rare variant. A few countries have adopted a mixed system in which some representatives are chosen in SMDs and others are elected by PR.

Older democracies tend to use one system or another for historical reasons. Newer democracies and those that have undergone major constitutional reforms are more likely to use systems like those of neighboring countries or their former colonial rulers (SMDs in the Americas and PR in Europe, for example) or to use one of the new systems.

In addition to electing representatives and executive officers such as presidents, voters sometimes vote directly on important issues, especially constitutions or constitutional amendments. This practice, called a referendum, was pioneered by Switzerland and has become increasingly common throughout the world.

ELECTORAL SYSTEMS IN LEGISLATURES AND OUTSIDE GOVERNMENT

Voting is also important within legislatures: Governments and laws must be approved by a majority of representatives. Secret ballots are uncommon in legislatures because they make it difficult for constituents to hold legislators accountable. In addition, when parties are strong, legislators almost always vote as their party leaders direct. The result is that a government in a system with strong parties wins nearly every vote, especially in the typical parliamentary system, where a government must have a majority of the seats in the legislature to take power in the first place.

The electoral systems used outside government often mimic governmental systems. For example, the members of a large club usually elect a board of directors and a president and other executive officers. However, there may be important differences. For example, many organizations
use open voting rather than a secret ballot, and in corporations the shareholders have as many votes as they own shares rather than one vote each.

**HOW DO PEOPLE DECIDE WHOM TO VOTE FOR?**

Many factors enter into citizens’ decisions about how to vote, and with the exception of ethnicity in an ethnically divided country no single factor overshadows the rest. Profession and economic class, religion, gender, region, the values instilled by parents, and longtime identification with a party can all play a role, as can events during the lifetime of a voter, such as the Great Depression and the 9/11 attacks. This complexity is probably for the best because having voters pulled in many different directions by cross-pressures tends to moderate conflicts and forces politicians to compete for votes.

Researchers generally agree, however, that except in patronage systems, voters rarely vote on the basis of narrow self-interest; they are more likely to vote on the basis of the interests of a large social group or the country as a whole. Citizens also tend to vote retrospectively, rewarding or punishing incumbents for the results of previous years, especially economic results, rather than guessing how candidates may perform in the future.

**VOTING PATTERNS**

Political scientists often study voting patterns to determine partisan preferences among selected voter groups. Voter groups, such as those based on income levels, education levels, gender, age, regional location, religion, race, or ethnicity, have historically changed their partisan preferences at times in a process called realignment.

Political scientist V. O. Key Jr., in “A Theory of Critical Elections” (1955), defined realignment as occurring when cross-cutting issues tear apart old partisan alliances and create new ones during an election cycle. For instance, in the 1930s, American president Franklin Roosevelt’s New Deal policies of union rights, government jobs programs, and social welfare caused large groups of voters who had previously voted Republican to switch to the Democrats.

Political scientist Walter Dean Burnham (1970) elaborated on the critical election theory of American politics, finding a cyclical pattern of every thirty to forty years for such a phenomenon and stating that such elections tend to create a new majority political party for decades afterward.

Because no critical election has been apparent in modern American politics, more recent political science studies of voting patterns tend to focus on the more gradual realignment processes that appear to have occurred since the 1950s or on the concept of dealignment, a belief that partisan attachments among voters are in decline. Studies of modern voting patterns outside of the United States also usually examine long-term realigning processes or a decline of long-term partisan attachments among voters.

Throughout history, democratic elections and partisan divisions around the world have often been organized along regional, ethnic, and religious lines. Class distinctions in voting patterns became important in many countries in the late nineteenth and early twentieth centuries. And by the end of the twentieth century, partisan voting differences related to race, educational level, age, and gender also became apparent in many countries.
While specific issues are important in explaining some of the partisan divisions and voting patterns, shared cultural attitudes toward government, society, and other groups often provide a stronger explanation. Examples are plenty among democracies of one group in society favoring a political party while another group in historical, social, or political opposition to the first group favors another political party.

AMERICAN HISTORICAL VOTING PATTERNS

In the United States, regional divisions became strong immediately prior to and after the Civil War of 1861–1865. Following the war, many northern parts of the United States, which had favored the abolition of slavery, supported the new Republican Party, while most white voters in the southern United States, who had opposed abolition, favored the Democrats. While the South also had a large African American population, most of that population was prevented from voting through intimidation and legal measures for much of the period between 1877 and 1965.

These regional divisions strengthened in the 1890s when a Populist agrarian and fundamentalist Christian movement took over the Democratic Party, and most Catholic immigrant populations in the northern United States joined northern Protestants in voting solidly Republican for the following forty years. However, Catholic voters in New York City remained mostly Democratic, and by the 1910s and 1920s, the majority Republican Party had split between a conservative wing and a progressive wing.

During the years of the Great Depression in the 1930s, Democratic president Franklin Roosevelt put together a “New Deal coalition” of support for the new majority Democratic Party by supporting new social welfare programs and union rights for working-class Americans, including Catholics, Jews, and African Americans in the North, as well as government reforms to appeal to progressive, educated voters and infrastructure spending to continue the support from southern white voters.

However, a party that tried to create a coalition of northern progressive voters, African Americans, and southern white conservative voters in the United States was doomed not to last, and by the 1960s, the Democratic New Deal coalition fell apart over such issues as equal rights for African Americans, the Vietnam War, environmental and consumer regulations, religious and family values, and gun control and responses to crime.

Prior to the 1960s, both the Democrats and the Republicans in the United States were catchall parties containing members and politicians from all ideological persuasions. But the realignment that began in the 1960s made the Republicans into a clearly conservative party favoring less government regulation, more military spending, imposition of the death penalty for violent crimes, opposition to limits on gun ownership, and support for traditional cultural values such as prayer in schools and opposition to gay marriage. Much of this shift in Republican ideology came from the strengthened role of southern politicians and voters in the party. The Democrats took stances opposite to the Republicans on most of those issues. Moderates did remain in each party, however, sometimes taking positions closer to the majority from the other party.

MODERN AMERICAN VOTING PATTERNS

This change in U.S. voting patterns has led to what many in the American media labeled the division of the “red states and the blue states,” named for a color-coded map used in the 2000 presidential election showing which states voted for the Republican presidential candidate and which voted for the Democratic candidate. On this map, Republican states were red, with Democratic states blue.

American voting patterns had evolved in the early twenty-first century to the regional opposite of what they had been a hundred years earlier. In the four presidential elections occurring between 1992 and 2004, the Democratic Party swept almost entirely the states of the Northeast and Pacific Coast areas as well as the states bordering on the Great Lakes in the Midwest region. The Republican Party during those elections swept almost entirely the states of the South and of the center of the country west from the Great Lakes through the Rocky Mountain region.

Strong racial and religious voting patterns also emerged in the United States over the period after the 1950s, with African Americans and Jewish Americans overwhelmingly supporting the Democrats, and the most religious white Americans strongly favoring Republicans.

While a majority of higher income U.S. voters continued to support the Republican Party in the early twenty-first century because of the party’s stance on low taxes, voting patterns based on educational levels began to change after the 1950s. Over the following fifty years, while the voters with the lowest educational levels and lowest incomes tended to remain as Democratic supporters, the voters with the highest educational levels, with graduate degrees, also became more Democratic, making the party to some extent a coalition of the most educated and least educated. The Republicans were at their strongest among those who had completed some years of university but had not finished.
A gender gap also opened up in the United States during the 1980s and continued into the twenty-first century. In every presidential election from 1988 to 2004, women preferred the Democratic presidential candidate, while men preferred the Republican presidential candidate, according to polls.

The presidential election of 2004 also showed the beginning of a possible new generation gap in American voting patterns, with voters under age thirty preferring the Democratic candidate for president, and older voters preferring the Republican.

MODERN VOTING PATTERNS AROUND THE WORLD

Such voting patterns and divisions of voter groups can be found in most other countries with democratic elections. Traditional economic class divisions between working-class voter support for left-wing parties and middle-class and upper-class support for right-wing parties in Europe were common for much of the twentieth century, but many of those divisions began to blur by the end of the century as some voters focused more on noneconomic issues.

Regional divisions in voting patterns have been strong in many countries. In Canada, the Conservative Party dominated in the western part of the country in the early twenty-first century, while the Liberal Party dominated the most populous province of Ontario, and parties advocating independence for Quebec tended to dominate politics in that province.

In the United Kingdom, the Conservative Party in the early twenty-first century had trouble winning any parliamentary seats in the northern part of England, and in Scotland and Wales, limiting its ability to form a new majority in the House of Commons. Voting patterns in many other European countries showed a strong regional basis in the early twenty-first century, with a former Communist party winning many votes in the former East Germany in German elections, a Northern League regional party in Italy participating in government coalitions, and Basque and Catalan regional nationalist parties winning a number of seats in the Spanish Cortes Generales.

VOTER TURNOUT

Voter turnout is a political phenomenon related to voting patterns, with voter turnout usually being defined as the percentage of the voting-age population who participate in an election, though the exact method by which turnout is measured can vary by country. In general, the United States and Switzerland have long had the lowest voter turnout among economically advanced countries, in part because of the frequency and complexity of elections in those countries. In the United States, only about half of adults were voting in presidential elections by the end of the twentieth century, with far lower numbers for other types of elections.

While turnout in other economically advanced democracies was generally much higher than in the United States during the 1900s, the trend in most countries has been toward declining turnout closer to the American tradition, with younger and less educated voters in particular among the least likely to participate in elections. Such a global decline in voter turnout may also have implications for changes in voting patterns throughout the twenty-first century.

VOTING RIGHTS ACT

The renewal was preceded by debates about whether the VRA was still necessary. The VRA is and has been one
of the most important laws in American history. Aimed at eradicating systematic discrimination against minorities and specifically at securing their voting rights, the VRA enabled the federal government to take affirmative steps toward ensuring racial equality and political fairness. Nonetheless, the renewal and extension of the VRA in July 2006 indicated that the battle to achieve nationwide political fairness was not over.

BACKGROUND AND GENESIS
The Voting Rights Act was signed into law by President Lyndon Johnson on August 6, 1965. The act was passed essentially to enforce the provisions of the Fifteenth Amendment, which states, “The right of citizens of the United States to vote shall not be denied or abridged by the United States or by any State on account of race, color or previous condition of servitude.” Despite the passage of the Fifteenth Amendment, along with the Thirteenth and Fourteenth Amendments to the Constitution, blacks systematically had been denied access to the franchise and the free exercise of their constitutional rights for the better part of a century.

The president’s determination to introduce the VRA was crystallized by the events of February and March 1965. The Reverend Martin Luther King had been arrested in Selma, Alabama. Peaceful protest marches ensued as King and other civil rights workers attempted to organize resistance to the institutionalized system of racial discrimination known as Jim Crow. The peaceful marches were met and dispersed by police violence. Clergy and other marchers were beaten and in some cases killed.

On March 7 marchers seeking to march from Selma to Montgomery were stopped on the Edmund Pettus Bridge leading out of Selma. There the marchers were beaten in another outbreak of police violence. This time, however, the violence was broadcast on national television.

On March 15, 1965, President Johnson spoke to a special joint session of Congress. In that speech he acknowledged that despite the passage of the Fifteenth Amendment black voters had been prevented systematically from exercising the franchise: “Experience has shown that the existing processes of law cannot overcome systematic and ingenious discrimination. No law that we now have on the books—and I have helped to put three of them there—can ensure the right to vote when local officials are determined to deny it” (Johnson 1965).

THE VOTING RIGHTS ACT OF 1965
The key provisions of the VRA were as follows:

- Section 2 of the act essentially restated the Fifteenth Amendment: “No voting qualification or prerequisite to voting, or standard, practice, or procedure shall be imposed or applied by any State or political subdivision to deny or abridge the right of any citizen of the United States to vote on account of race or color.”
- Section 4 explicitly forbade the use of literacy tests or other devices to deny citizens access to the franchise or the polling booths.
- Section 5 imposed “preclearance requirements” on any state or political subdivision that as of November 1, 1964, had used literacy tests and in which less than 50 percent of the voting-age population was registered to vote or in which less than 50 percent of registered voters voted in the presidential election of 1964.

In any political subdivision that met those criteria Section 5 required that the government submit any change to a “voting qualification or prerequisite to voting, or standard, practice, or procedure with respect to voting different from that in force or effect on November 1, 1964” to the United States District Court for the District of Columbia or the United States Department of Justice for approval. Section 5 thus was designed to prevent surreptitious or invidious attempts by local or state governments to continue to disenfranchise minority voters despite the intent of the VRA.

CONTROVERSIES
Several controversies arose as a result of the VRA, and all of them led to Supreme Court litigation. The first dealt with the scope of the act. What actually constituted a “voting qualification or prerequisite to voting, or standard, practice, or procedure with respect to voting”? Local officials who tried to resist the VRA took advantage of that ambiguity to craft subtle but effective practices that would limit the capacity of minorities to vote. As Abigail Thernstrom noted in 1987, “By 1969 public officials in Mississippi and elsewhere had made all too plain their readiness to alter the electoral environment by instituting, for instance, county-wide voting, eliminating the single member districts from which some blacks were likely to get elected” (Thernstrom 1987, p. 4).

In 1969 in Allen v. State Board of Elections the Supreme Court heard challenges to such laws passed by several southern states. The states argued that because the changes had no impact on black voters’ access to the polls, they were not covered by the VRA. However, in striking down those laws, the Supreme Court ruled that the franchise entailed more than mere access to the polls. The challenged laws included the following:

- A 1966 Mississippi law that allowed counties to change the manner in which their boards
supervisors were elected. Instead of using districts, they could use at-large elections.

- Another Mississippi law that allowed the boards of education in eleven counties to appoint the superintendent of education (instead of electing the superintendent).
- A Mississippi law that changed the requirements for independent candidates running in general elections.
- A Virginia law that changed the requirements for casting write-in ballots.

In striking down those laws, the Court ruled:

The Voting Rights Act was aimed at the subtle, as well as the obvious, state regulations, which have the effect of denying citizens their right to vote because of their race. Moreover, compatible with the decisions of this Court, the Act gives a broad interpretation to the right to vote, recognizing that voting includes “all action necessary to make a vote effective.” We are convinced that in passing the Voting Rights Act, Congress intended that state enactments such as those involved in the instant cases be subject to the 5 approval requirements. ([Allen v. State Board of Elections, 565–566, internal citations omitted])

Thus, the Court expanded the scope and definition of the franchise to protect it from pernicious attempts to constrain its exercise.

Another major controversy arose in 1982. As it originally was written, the VRA could have been interpreted to require plaintiffs to forbid only those electoral arrangements which had been passed with the intent of diluting minority voting power. In 1982 Congress rewrote Section 2 to require only a demonstration that a challenged law had the effect of diluting minority voting strength. Legislative intent did not matter.

In *Thornburg v. Gingles* (1986) the Supreme Court sustained the new effects standard. *Gingles* thus placed a great deal of pressure on the states. It led to extensive efforts by the Justice Department to require states to draw legislative and congressional districts in a manner that would allow minority voters to constitute an electoral majority. That practice led to the creation of so-called majority-minority districts with truly bizarre shapes and gave rise to another controversy: If districts drawn to shut minority voters out of politics were unconstitutional, could districts drawn to ensure their chances of election survive constitutional scrutiny?

In *Shaw v. Reno* (1993) the Court ruled that a redistricting scheme that was “unexplainable” on grounds other than race would violate the equal protection clause of the Fourteenth Amendment. If the record indicated that racial considerations had played a determining role in the construction of a challenged district and if the district’s shape indicated that the legislature had forsaken “traditional districting principles” to such an extent that its outline was “highly irregular,” “bizarre,” and “irrational on its face” (*Shaw*, 648), the redistricting plan would run afoul of the equal protection clause of the Fourteenth Amendment.

*Shaw* rewrote the rules of the districting process. *Gingles* had indicated that if states did not draw districts to enhance minority representational opportunities, they were guilty of vote dilution in violation of Section 2 of the VRA. According to *Shaw*, if they went too far in drawing majority-minority districts, particularly in states that did not have large demographic concentrations of African American voters, they risked a Fourteenth Amendment challenge.

**SHAW AND THE DOUBLE STANDARD OF VOTING RIGHTS**

After *Shaw* voting rights law was based on a double standard. Districts drawn to harm minority voters were unconstitutional, but districts drawn to help them were also unconstitutional even though it was constitutionally permissible to draw them to help other groups, such as incumbents, urban and rural voters, Democrats and Republicans, and other ethnic groups. In subsequent rulings the Supreme Court resolved that double standard by modifying its stand against racial gerrymandering.

In *Miller v. Johnson* the Court declared congressional districts in Georgia unconstitutional because the legislative record clearly demonstrated that they had been drawn with the explicit intent of maximizing the number of majority-minority districts. In her concurrence, however, Justice O’Connor indicated that the double standard in *Shaw* was problematic:

The standard [for assessing the constitutionality of districts] would be no different if a legislature had drawn the boundaries to favor some other ethnic group; certainly the standard does not treat efforts to create majority-minority districts less favorably than similar efforts on behalf of other groups…. Application of the Court’s standard does not throw into doubt the vast majority of the Nation’s 435 congressional districts, where presumably the States have drawn the boundaries in accordance with their customary districting principles. That is so even though race may well have been considered in the redistricting process. (*Miller*, 928–929, O’Connor, J., concurring)

O’Connor thus acknowledged that factors such as race and ethnicity are part of the redistricting process.
But, she said, the Shaw standard at least allowed the Court to police “extreme instances of gerrymandering.”

ERADICATING SHAW’S DOUBLE STANDARD

A majority of the Court finally acknowledged the tensions in its voting rights jurisprudence. In Easley v. Cromartie (2001) the Court declared majority-minority congressional districts in North Carolina constitutional despite their bizarre shapes because they were the product of a multitude of factors only one of which was race. In so doing, the Court set forth a standard of proof that made it easier for states to avert a Shaw challenge while simultaneously upholding the goals of the VRA.

So long as states could demonstrate that some other factor besides race played an important role in the drafting of legislative district lines, they could defend a districting scheme by explaining that race did not “predominate” (Easley, 258). The Court thus drew upon a statement made by Justice O’Connor in Bush v. Vera: “If district lines merely correlate with race because they are drawn on the basis of political affiliation, which correlates with race, there is no racial classification to justify” (Bush v. Vera, 968). Thus, the Court explained that “the Constitution does not place an affirmative obligation upon the legislature to avoid creating districts that turn out to be heavily, even majority, minority. It simply imposes an obligation not to create such districts for predominantly racial, as opposed to political or traditional, districting motivations” (Easley, 248).

Easley allowed courts to look at a racially remedial gerrymander and declare it nothing more than a partisan or incumbent one. By declaring that race had to be the predominant factor in a redistricting plan, the Court enabled states to defend their plans by offering a plausible partisan alternative explanation for their districting decisions. In this respect the states could cloak a racial gerrymander in partisan clothing and move on.

RETROGRESSION AND PRECLEARANCE

Although the line of cases from Shaw to Cromartie addressed the manner in which states and the Justice Department could remedy claims of vote dilution, the Supreme Court also had to address key issues concerning the preclearance provision in Section 5. Specifically, the Court had to determine the scope and definition of “retrogression.” In Georgia v. Ashcroft (2003) the Supreme Court ruled that a reduction in the number of majority-minority districts in a covered jurisdiction did not necessarily amount to a retrogression in minority voting power. In some cases states could draw so-called minority “influence” districts. In those districts, it was argued, minority candidates could win even though the districts were not composed of a majority of minority voters.

The development of this strategy for enhancing minority voting strength was a reaction to the Shaw line of cases. Scholars such as Sam Hirsch (2002) had demonstrated that minority candidates could win elections in minority influence districts if their campaigns were crafted carefully. Insofar as such districts were not drawn to ensure that minority voters constituted a majority of the population, they did not run afoul of the standard set forth in Shaw. Speaking for the Court, Justice O’Connor stated:

a court should not focus solely on the comparative ability of a minority group to elect a candidate of its choice. While this factor is an important one in the § 5 retrogression inquiry, it cannot be dispositive or exclusive … to maximize the electoral success of a minority group, a State may choose to create a certain number of “safe” districts, in which it is highly likely that minority voters will be able to elect the candidate of their choice. Alternatively, a State may choose to create a greater number of districts in which it is likely—although perhaps not quite as likely as under the benchmark plan—that minority voters will be able to elect candidates of their choice. (Ashcroft, 480)

She concluded: “Section 5 gives States the flexibility to choose one theory of effective representation over the other” (Ashcroft, 482).

IMPLICATIONS AND FEARS

In some aspects the decisions in Easley v. Cromartie and Georgia v. Ashcroft represent a great victory and resonate with the spirit of the VRA. They permit the practice of drawing districts to help racial and ethnic minority voters gain representation that has benefited other groups of voters throughout American history. However, they do so in a manner that prevents unabashed attempts to draw electoral districts that are guaranteed to produce a particular result. In this respect they manifest a bizarre irony: The battle to end discrimination against minority voters by gerrymandering electoral districts has been won by giving minorities the same chance as every other political group to gerrymander electoral districts in their favor.

The controversy surrounding ways to define and prevent minority vote dilution and retrogression remains a key focus of the VRA. However, although academic debates about the superiority of majority-minority districts or minority influence districts endure, they demonstrate the positive impact of the VRA. Instead of fighting to protect minority voting rights, scholars and practitioners now debate how best to protect the franchise.

Despite these advances the possibility that some parts of the VRA might have expired in 2007 generated contro-
versy and debate. Studies by many organizations ranging from the American Civil Liberties Union to the National Commission on the Voting Rights Act demonstrated that in many ways many Americans still were unable to exercise the franchise freely.

The renewal of the language provisions manifested the scope and complexity of expanding voting rights protections further. As the election of 2000 and the passage of the Help America Vote Act demonstrated, many obstacles to the truly free exercise of the franchise have continued to exist. They range from making sure that non–English speakers are able to register and vote to ensuring that voting procedures are not confusing and that voting machines function properly.

Thus, although the VRA and the ensuing Supreme Court decisions have resulted in a fairer process of drawing voting districts and a means by which the federal government can be called on to oversee changes in local election laws, the renewal of the nonpermanent provisions of the act in 2007 demonstrates the need to continue policing the electoral process and the renewed national commitment to preserving the integrity of American democracy.

VOTING SCHEMES

Voting schemes are methods of combining individual preferences to arrive at the aggregate preferences of the group. The study of the effects of different voting schemes is called social choice theory. Perhaps the seminal work in the modern study of voting schemes is Kenneth Arrow’s Social Choice and Individual Values (1951). In that work, Arrow lays out five attributes that ought to exist in any fair and just voting scheme, then goes on to say that no scheme can simultaneously incorporate all five attributes.

Arrow’s impossibility theorem implies that there is no one best voting scheme. To that end, democracies have experimented with a number of different voting schemes. The question of which voting scheme to use is not merely trivia, because the type of voting scheme that is adopted almost certainly has effects on electoral outcomes. For example, consider the following election with three candidates, one hundred voters, and three types of voters:

- There are thirty-five type-one voters who prefer candidate A most, then candidate B, then candidate C.
- There are thirty-three type-two voters who prefer candidate C most, then candidate B, then candidate A.
- There are thirty-two type-three voters who prefer candidate B most, then candidate C, then candidate A.

Mark Rush
It is easy to see that the election above is not decisive under majority voting, since no candidate garners a majority of votes. Two very popular voting schemes are plurality rule, whereby the candidate who receives the most votes wins, and majority rule with runoff, whereby the top two vote-getters in the first election compete in a second election to determine the winner. Under plurality rule, which is used in countries such as Great Britain and Canada, candidate A would win with 35 percent of the vote. Under majority rule with runoff, which is used in countries such as France and Brazil, candidates A and C would go to the runoff election, where candidate C would win with 65 percent of the vote (since all type-three voters would join with type-two voters in supporting candidate C).

One important determinant of the voting scheme is the country’s type of regime. Democracies can differ on a number of variables. For example, in unitary systems, the country is governed in a single unit, often the parliament, which elects a prime minister to serve as an executive. Great Britain, Israel, and Chile are examples of unitary states. At the same time, other countries are federal systems, whereby governing authority is held in different locations. Often, states or provinces share governing authority with a national government. Examples of federations include the United States, Russia, and Brazil. Smaller countries often tend to be unitary systems, whereas larger ones are more likely to be federations, although there are exceptions. For example, Switzerland is a relatively small country, but has a federal system.

Many unitary countries use proportional representation (PR) electoral systems, although Great Britain and other Westminster systems are notable exceptions. In PR systems, parties receive representation in the nation’s legislature that is proportionate to the percentage of votes the party received in the last election. In these systems, parties prepare lists of candidates. In open-list systems, such as those of Chile and Sweden, voters can choose individual candidates from the parties’ lists. In contrast, voters in closed-list systems, such as that of Israel, select only the party, and the choice of the candidates is left up to party leaders. PR systems tend to have very disciplined parties within their legislatures, meaning that party members virtually always vote the same way on legislative proposals. This is because parties control the lists, and can therefore punish rogue representatives by keeping them off the lists.

On the other hand, many federal systems and some unitary systems use winner-take-all elections, whereby one candidate wins an election to represent the people living in a particular geographic area. This is how elections work in, for example, the United States and Great Britain. According to Duverger’s law (1963), systems that use winner-take-all elections, sometimes called first-past-the-post elections, tend to have only two parties. This is because such systems provide no incentive for coming in second place. In winner-take-all systems, a candidate who receives 45 percent of the vote wins nothing, whereas such a candidate would receive about 45 percent of the legislative seats in a PR system. For this reason, politicians are better off coalescing into two parties prior to an election in winner-take-all systems, but do not face that same incentive in PR systems. As a result, PR systems tend to have many small parties, whereas winner-take-all systems tend to have only two.

Furthermore, political activists often advocate for implementing new voting schemes because the voting scheme selected has such a strong effect on the political landscape of a democracy. For example, we saw above that voting schemes affect the number of parties in an electoral system. Other systems are advocated because they could increase the amount of representation minority groups receive. For example, cumulative voting is a voting scheme in which voters elect several representatives, and have the same number of votes as there are empty seats to fill. Voters may opt to use those votes to vote for different candidates, or they may cumulate their votes onto one candidate whom they most prefer. In this way, advocates argue, members of minority groups can cumulate their votes onto one candidate, thereby increasing the chances that their one candidate will win. At the same time, advocates of approval voting argue that their system encourages voters to accurately report their true preferences, rather than misstating them in an effort to gain some strategic advantage. In this type of system, voters deem each candidate either “approved” or “not approved,” and the candidate with the most “approved” votes wins. Furthermore, advocates of single transferable voting, often called instant runoff voting, argue that their system discourages negative campaigning and provides incentives for sincere voting. In this system, voters provide a ranking of candidates from most to least favored. Counting votes entails adding up all of the most-favored votes and dropping the candidates with the lowest number of votes. Then, the votes of all those who ranked the dropped candidate first transfer to their next-most-preferred candidate, and the process continues until a winner is determined.

VULNERABILITY

The concept of vulnerability is derived from the Latin vulnus or "wound." Its etymology signifies the human potential to be wounded, that is, to experience physical trauma. In modern usage, the notion refers to both physical and psychological harm: It indicates human exposure to psychological harm, moral damage, or spiritual threat. Vulnerability more generally includes our ability to suffer psychologically, morally, and spiritually rather than simply a physical capacity for pain from our exposure to the physical world. Our common human vulnerability as illustrated by our morbidity and mortality can be regarded as the basis for shared human rights, such as the right to life itself. Modern revulsion against torture in international legal codes illustrates the common theme of vulnerability running through human rights declarations.

In referring to hazards and disasters, the notion of vulnerability draws attention to the risky relationship between people and their natural environments. Various major disasters in modern times—Hurricane Katrina (2005), the tsunami disaster (2004), the earthquake in Kobe, Japan (1995), and severe droughts across Africa—have encouraged governments and international agencies to seek improved measures of risks and vulnerabilities.

More recently, vulnerability refers in computer sciences to weaknesses in a system that permit an attacker to compromise the integrity, security, and confidentiality of the system, its data, and its applications. Computer vulnerability of a construct exists when many program faults can be traced to it. One important task of computer software programs is to devise appropriate tools that can assist in the discovery and removal of such vulnerabilities as input validation errors.

Various attempts have been made to create standardized measurement systems to provide accurate information on risks and vulnerability. For example, in the realm of information technology security, the U.S. National Infrastructure Advisory Council has promoted the Common Vulnerability Scoring System, which provides universal standard ratings of vulnerabilities. The challenge is to get these measurement criteria universally accepted. In 1973 the United Nations University was created and now incorporates the Institute for Environment and Human Security (UNU-EHS), which exists to study acute environmental hazards. Its journal, SOURCE, has published research that attempts to provide coherent and unified criteria for understanding hazards.

Vulnerability research covers a range of complex fields, such as political ecology, security studies, and disaster and risk management. This research is important for organizations trying to reduce vulnerability. Major research questions are concerned with measuring, assessing, and preventing vulnerability. Although much of this research is concerned with assessing environmental risk, social vulnerability is an important branch of vulnerability research. In this context, vulnerability research considers how different social groups are exposed to natural hazards and major social disruptions. One example is research on the vulnerability of isolated elderly men in the inner-city areas of Chicago who were found to suffer an "excess" of fatalities (as compared to other social groups in the city) during the heat wave of July 1995.

Social risk management (SRM) is a developing academic field associated with attempts to limit poverty and analyze the causes of poverty, including the interaction between empowerment, security, opportunity, and poverty. The threat of SARS (severe acute respiratory syndrome) and avian influenza has illustrated the vulnerability of modern societies, especially in the developing world, to the globalization of acute infections, to which traditional quarantine techniques are inadequate policy responses. There is a close relationship between SRM and world development programs that attempt to predict poverty and address its causes. These developments now fall under the general heading of prevention science, which applies the social sciences to a broad range of modern crises on the model that has been developed by public health strategies.

Risk assessment of vulnerable groups plays an important role in public health programs. An early illustration can be taken from the research of George Brown and Tirril Harris (1978) into the social causes of depression among young women in London. They found that the "vulnerability factors" included the loss of a mother before the age of eleven, lack of employment, and three or more children at home under the age of fourteen. The most significant protection against depression was the presence of an intimate friend. An effective social network lowers the risk of clinical depression. Adolescent children are at risk, and suicides among young people have in recent years increased dramatically. In the United States, suicide is the...
third leading cause of death for twenty-four-year-olds and the sixth leading cause of death for children between the ages of five and fourteen. Various agencies—the American Psychological Association, Usenet newsgroups, and the National Clearinghouse on Child Abuse and Neglect Information—provide checklists to assess behavioral changes in young people that might indicate increasing risk of self harm, including suicide, such as a change in eating and sleeping habits, withdrawal from friends, violent behavior, and drug use. The Behavioral Risk Factor Surveillance System (BRFSS) is the world’s largest ongoing telephone health survey system tracking health conditions and risk behavior in the United States through fifty state health departments.

With the aging of populations in developed societies, the leading causes of death have changed from infectious disease in infants to geriatric conditions—stroke, heart attack, and cancer—among the elderly. For example, the American Heart Association has identified several risk factors associated with heart disease, such as increasing age, male sex, and hereditary. There are also lifestyle factors that make people vulnerable, such as smoking, physical inactivity, obesity, and diabetes mellitus. Starting with research in the 1950s, psychologists argued that there was an “executive disease” among white-collar employees in the corporate world. American cardiologists claimed that type-A men were competitive and ambitious, and their corporate lifestyle made them vulnerable to heart attack as a consequence of high levels of stress. Medical debate has concentrated on assessing whether vulnerability to disease is produced by environmental factors (such as pollution) that can be modified by legislation and political intervention, or whether the primary causes are genetic, where medical intervention (such as genetic counseling for Huntington’s disease) involves long-term strategies. The evidence suggests that disease is a product of both environmental and genetic causes, and requires appropriate strategies to address both social and genetic dimensions.

The growth of prevention sciences (for consistency with above changes) can be seen as a response to the common perception that the world is becoming increasingly risky. The economic and social assessment of risk arose from attempts to calculate profit and loss in the growing international trade in the sixteenth and seventeenth centuries. With modernization, there is greater interconnectivity between societies, making the rapid spread of infectious disease more problematic. With technological development, the risks of industrial pollution and hazard are much greater. With growing sophistication in military technology, the risk of intended and unintended military disaster is also much greater. In short, with modern social change, human vulnerability and institutional precariousness increase.

These social and technological changes were summarized by sociologist Ulrich Beck in his *Risk Society*, which was originally published in Germany 1986. The concept of a “risk society” greatly stimulated social science research into uncertainty, risk, and hazard. Beck developed a sociological perspective to show why disasters such as the chemical leak at Bhopal (1984), accidents at the nuclear power plants at Three Mile Island (1979) and Chernobyl (1986), and global warming were products of modernization, involving the intensive application of technology to transform the environment to satisfy human needs. Such risks were the unintended consequences of technological modernization. The modern growth of “green” political parties and their electoral successes can also be treated as an indication that the general public is aware of modern vulnerabilities, of which the prospect of global warming is probably the most significant.

WAGE AND PRICE CONTROLS

Examples of rulers and governments attempting to control prices and wages can be found in distant history, but comprehensive wage-price controls or similar voluntary programs for anti-inflation purposes are really a twentieth-century development. Simple microeconomic analysis suggests that controls that set prices and wages too low will create product or labor shortages. However, under wartime circumstances, governments have sometimes been willing to allow shortages and rationing. And in peacetime, the rationale for wage-price controls was for many years centered on the idea that prices and wages, especially the latter, could be administered.

In the United States and other countries, wage-price controls were enforced to varying degrees during the two world wars. The United States also imposed controls during the Korean and Vietnam wars. Voluntary wage-price programs were initiated during the Kennedy-Johnson and Carter administrations. After World War II, various European countries adopted “incomes policies” similar to the voluntary programs later installed in the United States. Controls during the two world wars and the Korean War were part of larger schemes aimed at diverting resources for military purposes. Beginning in the 1960s, attempts to influence or control wages and prices had a more general macroeconomic justification.

American participation in World War I was relatively brief but involved a diversion to military purposes of perhaps a fifth of the nation’s gross domestic product (GDP). Large corporations had developed by that time, so control administrators could interact with the heads of these firms. The idea developed that controls could be achieved by involving a few key captains of industry. Just as successful corporations engaged in internal planning, so too could the national economy be planned and—in wartime or other emergencies—controlled. As might be expected, in competitive industries—such as foodstuffs and coal—World War I controls did produce temporary shortages. However, formal ticket-based consumer-rationing schemes were not adopted and reliance instead was placed on patriotic appeals to reduce demand. Unions expanded during the war, and government pushed for industrial peace and production uninterrupted by strikes. In some instances, notably involving the railroads, the authorities seized enterprises when labor strife was threatened.

The World War I experience with controls on wages, prices, and resource allocation tended to reinforce notions of the practicality and virtue of national economic planning. These ideas carried over into the New Deal during the Great Depression and—when World War II arrived—into a cadre of individuals to staff wartime economic planning agencies and, in particular, wage-price control programs. Because of its duration and scale, World War II controls were more extensive than in World War I. Military expenditures exceeded 40 percent of GDP at the peak of the war.

Agencies were established to control prices, wages, and more general resource allocation. Formal ticket-based rationing of consumer goods applied to food, gasoline, and other products. The result was a retarding of officially measured inflation. In some cases, however, black markets developed for goods in short supply. The economic meaning of price indexes based on official prices at which goods were not freely available can be debated. However, the
overall system of controls was justified on the basis of fairness, wartime resource needs, and appeals to patriotism.

Unions had already become powerful during the New Deal, and a pattern arose that carried on into the postwar wage-price programs. Specifically, the wage authorities—the War Labor Board in World War II—established a standard for pay, albeit one laden with exceptions. Price controls—under the Office of Price Administration—were then largely based on markups over costs. In a relatively closed economy, interindustry goods purchases and their costs largely net out, making labor a major cost element. During World War II, the pay standard was based on the “Little Steel Formula,” a wage settlement reached with smaller steel firms. When strikes occurred during World War II for pay above the standard, enterprises were sometimes seized and workers were sometimes threatened with conscription. Inflation and labor disputes were repressed sufficiently so that when the war ended and decontrol commenced, there was a wave of strikes and a burst of measured inflation.

Although federal controls ended, local rent controls lingered in some local jurisdictions, notably New York City. The wage authorities during World War II had tended to allow exceptions to the standard for fringe benefits such as pensions. As a result, pensions and health insurance gained a foothold at the employer level, which expanded after the war into a company-based system of social insurance.

The World War II experience led to public expectations that wars meant consumer goods shortages. Hence, when the Korean War began in 1950, a surge in consumer buying and hoarding led to a jump in inflation and, eventually, a reinstatement of wage-price and resource allocation controls by the Truman administration. In broad terms, the controls followed the World War II model, with a price authority and a wage authority. The program was again generally based on control of pay, with price controls largely to be achieved by allowable markups over costs. However, the overall program was less extensive than before, partly because peak military expenditures during the Korean War were about 15 percent of GDP, a substantially lower ratio than in the earlier conflict.

Presidential authority during the Korean War was also more limited than in World War II. An attempt by President Truman to seize the steel industry during a labor dispute was rebuffed by the U.S. Supreme Court. When President Eisenhower took office in early 1953, the Truman-era wage-price controls were quickly dismantled. Decontrol did not lead to a sharp surge in inflation, in part because the anticipatory price surge had occurred before controls were imposed. Under Eisenhower, activity in the wage-price area was largely limited to exhortations aimed at moderate wage settlements and price behavior.

In the period after the Korean War, a theoretical base developed in academia for wage-price interventions, encouraged in part by the observation of European incomes policies. Such European policies typically involved centralized wage settlements though a tripartite negotiation between employer federations, union federations, and government. With unions at their peak in the United States, notions developed of wage-push inflation and resulting wage-price spirals. These concepts were combined with empirical studies of the “Phillips curve,” which depicted an unpleasant trade-off between wage inflation (and therefore price inflation) and the unemployment rate.

Essentially, the idea was that if wages could be made less “pushy” through some form of governmental intervention, the nasty trade-off of the Phillips curve could be repositioned to allow lower unemployment at a given inflation rate. Later, when the idea of a permanent Phillips curve was replaced by that of a non-accelerating inflation rate of unemployment (NAIRU), the same argument could still be advanced. Intervention aimed at making wages less pushy could lower the NAIRU. There were notions of “key” union pay settlements, which were then imitated elsewhere in the union sector and which spilled over into nonunion pay adjustments. If the key union settlements could be moderated, pay setting would be less inflationary.

The incoming Kennedy administration—whose economists were Keynesians with a focus on lowering unemployment—was particularly receptive to this concept. Under the Bretton Woods fixed exchange-rate system, the United States was committed to maintaining the value of the dollar relative to other currencies and the value of gold relative to the dollar. By the early 1960s, there was a dollar surplus and concern about the dwindling gold stock. Holding down inflation was seen as needed to defend the dollar by maintaining American cost competitiveness in world markets. But absent some other policy instrument, inflation moderation was also seen as requiring a higher level of unemployment than President Kennedy wanted. As a result, the Council of Economic Advisors under Kennedy (and later Johnson) put forward voluntary wage-price “guideposts,” with its wage standard to be based on the trend rate of productivity (seen as a little over 3 percent per annum) and prices to be based on markups.

Steel was again the center of a major dispute. The Kennedy administration intervened in a steel labor negotiation and achieved what it believed was a moderate pay settlement. When the industry subsequently raised its prices, President Kennedy demanded and ultimately received a price rollback. The guidepost program became more elaborate as time went on. But it eventually was
overcome by demand pressures in the labor market and union demands for wage increases above the standard, and it basically faded away.

Inflation became a political issue in the early years of the Nixon administration. In August 1971, President Nixon announced an end to the Bretton Woods system, disengaged the dollar from gold, and imposed a ninety-day wage-price freeze. Thereafter, mandatory controls on wages and prices were imposed, which then passed through a series of phases of varying intensity. The most elaborate was Phase II, which featured a tripartite Pay Board and a Price Commission. This model was subsequently imitated in Britain and Canada.

Although the Vietnam War was in progress, the Nixon controls were not part of a larger scheme to redirect resources to the military. Indeed, the peak ratio of military expenditures to GDP during the Vietnam War was about 10 percent—and that peak had already occurred under Johnson. Moreover, because of earlier ongoing cold war military spending, the ramp-up of such spending to accommodate the Vietnam War was less dramatic than in prior wartime situations.

The initial pay standard after the freeze was based on productivity plus an allowable rate of inflation, with price controls built—as before—on permissible cost markups. Some shortages occurred during the Nixon controls, notably involving meat and gasoline. The Nixon program was largely ended under President Ford in the spring of 1974, except for elaborate controls on oil prices. Ford replaced formal wage-price controls with a program of anti-inflation exhortation coordinated by a Council on Wage and Price Stability (COWPS). This program featured promotion of much-ridiculed WIN buttons (“Whip Inflation Now”) and various announced “inflation alerts.”

President Carter continued COWPS and returned in 1978 to a Kennedy-Johnson-type program of voluntary wage-price restraints, termed “guidelines” rather than guideposts. A wage standard of 7 percent was announced with various exceptions. Academics in the 1970s had toyed with using the tax code to reward employers and/or workers for complying with such pay standards or penalizing those who did not. Reflecting this academic work, the Carter administration proposed an elaborate (and probably unworkable) program of “real wage insurance,” which would have used tax rebates to protect complying workers from inflation above 7 percent.

Subsequently, a tripartite Pay Advisory Committee was established with a vague charter to support the 7 percent target. Congress never enacted the Carter tax program, and the Reagan administration quickly abandoned wage-price interventions altogether, relying on tight monetary policy at the Federal Reserve to reduce inflation. The mandatory controls on oil prices that Carter had inherited from Nixon and Ford led to very unpopular gasoline shortages, contributing to Carter’s defeat by Reagan in the 1980 presidential election.

Post-Korean wage-price interventions were based heavily on notions of wage-push and wage-price spirals. But starting in the mid-1950s, the union share of the workforce had begun to decline, a process that accelerated during the Reagan years and continued thereafter. In much of the developed world, similar union declines occurred. Thus, the intellectual rationale for wage-price interventions—mandatory or voluntary—largely has disappeared. In addition, wars after the Korean War have not entailed large shares of GDP. Absent the earlier military or macroeconomic justifications, it is unlikely that such programs will be used in the future.

The era of wage-price controls, guideposts, and guidelines, with its accompanying notions of dangerous wage-push pressures and wage-price spirals that needed to be restrained, has left a mark on macroeconomics. Contemporary economists often explain the concept of the NAIRU in language from the era of extensive unionization and collective bargaining. Low unemployment is often said to lead workers to “demand” higher wages or refuse to “accept” wage offers by employers. In fact, the conversion of labor markets to nonbargained pay determinations has created what past proponents of mandatory or voluntary wage-price programs had once hoped to achieve. The U.S. economy in the 1990s and thereafter operated with a relatively low NAIRU and without the inflationary tilt feared to exist in the period beginning in the 1950s. Given this institutional change, it is likely that the rhetorical legacy of mandatory and voluntary wage-price programs will eventually also disappear.

WAGES

Wages are remuneration for labor services, in the form of either cash or some other mechanism of compensation. Wages have been the subject of extensive empirical and theoretical inquiry, the focus of which has included causes and consequences of wage variation, implications of evolving labor market conditions, and the effects of wage increases on productivity and growth. Generally, these studies approach such questions through the prism of two alternative labor market circumstances: perfectly competitive markets, in which consumers and producers have no market power to affect prices, and imperfectly competitive markets.

THE LABOR MARKET UNDER PERFECT COMPETITION

Traditionally, economic analysis is predicated on the assumption that labor markets are perfectly competitive. For this to be reasonable, three criteria must hold: There must be no barriers to entry; agents must have complete information; firm and labor mobility must be costless. When these conditions obtain, wage rates of a given quality are determined by the intersection of the labor supply and demand curves. The labor demand curve reflects the marginal productivity of labor confronting profit-maximizing firms. The labor supply curve reveals the willingness of utility-maximizing individuals to supply labor at each conceivable wage. The intersection of these two curves determines the market clearing wage rate, at which all persons willing and able to work will find employment. In this framework, the wage rate is a market price that effectively allocates labor across alternative (and competing) uses.

One vein of the empirical work mentioned above is essentially rooted in this perfectly competitive framework. For instance, there is a tradition of fairly straightforward examination of inter-temporal wage patterns implicitly interpreted through the lens of perfect competition. Katz and Autor (1999) examine longitudinal wage data in the United States, revealing several interesting patterns. The ratio of wages of those in the ninetieth percentile of workers to those in the tenth percentile has grown substantially in recent decades. Large wage disparities have also been detected by education and experience levels. Nonetheless, wage gaps between white and black males and males and females overall have narrowed.

There is, however, no consensus regarding the causes of these structural changes. An often-cited theory explains wage differentials as a result of investments in human capital (e.g., through education, health, or training). Becker (1964) formalized this idea by demonstrating that greater human capital expenditures could account for empirically observed patterns of wage variation via their impact on the marginal revenue product of labor. This theory received empirical support from Mincer (1974), whose estimates of the returns to education were positive and increasingly significant with controls for years of experience in the labor market.

Numerous studies question this explanation of observed wage differences. For instance, Pritchett (2001) shows that education has contributed very little to economic growth. He speculates that, among other possibilities, this might reflect the irrelevance of knowledge transmitted through formal schooling (in terms of the skills actually required in the workplace). From a slightly different perspective, some (e.g., Spence [1974]) have argued that education contributes little directly to labor market productivity, but instead serves as a kind of signal for ability that allows employers to sort high and low ability workers.

Another avenue for wage variation generally approached through the framework of perfect competition is immigration. LaLonde and Topel (1991) consider
the impact of newly arrived immigrants on the wages of workers born in the United States as well as those who had immigrated to the United States earlier. They find that immigration has a negative, but small, impact on the wages of earlier immigrants and native-born workers who represent close substitutes (i.e., low skilled workers) for these more recent arrivals. This relationship attenuates as the tenure of earlier immigrants in the United States increases. Others (e.g., Borjas [2003]) have disputed these findings, claiming that they stem from the failure to control for the migration of native-born Americans to other cities and states.

A DEPARTURE FROM A PERFECTLY COMPETITIVE LABOR MARKET

The other major theoretical and empirical tradition focuses on possible market failure resulting in involuntary unemployment (a situation where workers willing to work at the prevailing market wage rate cannot find employment). Efforts to explain such failures have centered on two major theoretical possibilities: market failure rooted in the purposeful decisions of optimizing agents and failure as a consequence of government intervention.

The former possibility (failure stemming from the actions of optimizing agents) has received considerable research attention. To begin with, there is the obvious potential for a “menu costs” type situation: Firms may resist adjusting wages to a new equilibrium level if the transaction costs associated with doing so are sufficiently high. Another possibility that has attracted more interest is commonly referred to as “efficiency wages” (e.g., Akerlof and Yellen [1986]). This is the idea that wages might be set above market equilibrium for the purpose of inducing higher worker productivity and efficiency.

Several specific motivations for efficiency wages have been suggested. First, they might reduce shirking and increase the financial penalty associated with termination. Shapiro and Stiglitz (1984) demonstrate that in the face of limited monitoring resources firms are willing to pay efficiency wages for these reasons. Efficiency wages might also lessen turnover costs by rendering workers less likely to quit their jobs (more experienced workers tend to be more productive than new employees, whose training can also be costly). Particularly in the setting of lower income countries, higher wages can improve the health and overall well-being of workers (through greater food and health consumption), potentially raising their productivity. Finally, efficiency wages can help firms avoid adverse selection by encouraging more skilled (and thus more productive) workers to apply for jobs.

Another potential source of market failure comes from the timing of wage contracts. In essence, contracts offer a specified wage payment over some fixed interval of time during which there might be shifts in labor supply or demand (and hence in the fundamental equilibrium wage that would prevail in an unfettered market). However, such contractual agreements can prevent adjustment in wages toward these new equilibrium conditions (a situation referred to as “wage stickiness”). State intervention is another major reason that equilibrium conditions in the labor market may fail to obtain. For instance, a legally mandated minimum wage (a kind of price floor) may result in labor market disequilibrium if that minimum wage level is binding in the sense that it exceeds the equilibrium level that would emerge in its absence. Most empirical and theoretical work on the subject suggests that minimum wages that are binding in this sense yield, ceteris paribus, lower employment levels. However, a few studies (e.g., Card and Krueger [1994]) have received a great deal of attention for reaching the opposite conclusion. Card and Krueger (1994) examine the effects of an April 1992 minimum wage increase (from $4.25 to $5.05 an hour) by exploiting the fact that the increase was implemented earlier in some states than others. Employment levels before and after the change showed no signs of the decline anticipated in the face of an increase in the minimum wage: Employment levels actually increased. However, Card and Krueger (1994) have received a great deal of methodological criticism.

WAGES, COMPENSATING

Adam Smith was the first to suggest that persons in dangerous or unpleasant jobs should be paid a high wage. His example was extreme: public executioner. Smith reasoned that despite the black hood that conceals the executioner’s identity, people would not want that job unless they were paid additional compensation above the average wage for the community. Economists have since used the term compensating wages to refer to this additional compensation. The compensating wage hypothesis holds that compensating wages are generated in competitive labor markets to equalize the net benefit (wage minus risk) workers derive from safe and dangerous jobs. If true, the hypothesis and corresponding empirical estimates of the amount of compensating wages for different levels of risk have implications for occupational safety and health policy, workers’ compensation, and statistical estimates of the value of life.

Evidence for compensating wages is undeniable in high-profile and dangerous jobs such as iron workers constructing tall buildings, airline pilots, bounty hunters, ocean fishers, and coal miners. But these jobs comprise only a fraction of all jobs, and the associated risks are obvious. It is not clear that compensating wages are generated across all dangerous jobs throughout the economy. (See Mason 1995 for a critique of compensating wage differentials.)

The hypothesis requires that workers be mobile, informed about job hazards, rational, and risk averse. Most debate about the hypothesis has to do with mobility and information. Job attachment increases with age, marriage, and children in the family, but jobs can become more or less dangerous over time, and attached workers may not change jobs. In addition, some workers, especially poor ones, may not have much mobility if the only choice is between a dangerous job or none at all. Information is also problematic. Vehicle crashes and assaults are frequently overlooked by the public as likely job hazards, yet together they are responsible for 40 percent of all fatal injuries. The frequency of vehicle crashes helps explain why relatively low-wage occupations such as gardeners, construction laborers, traveling sales workers, pizza delivery drivers, garbage collectors, and farm workers face excessively high death rates. The rate of assaults helps explain why clerks in convenience stores and fast-food restaurants, as well as gas-station attendants, also face high death rates. In addition, even the strongest advocates for the hypothesis acknowledge that due to lack of information, compensating wages are unlikely to be paid for occupational diseases, yet job-related diseases cause roughly 60,000 deaths per year in the United States, compared to 5,000 injury deaths.

The empirical evidence with large data sets is mixed. The best evidence supporting the hypothesis derives from U.S. Bureau of Labor Statistics data on fatality rates across industries. But these industry data conflate blue-collar with white-collar jobs, and death rates across industries are correlated with historical interindustry wage differentials. For more than 100 years and within many developed countries, wages for blue-collar workers have been high in transportation, construction, and manufacturing, and low in services, wholesale, and retail trade, independent of job hazards. Studies suggest that when interindustry wage differentials are accounted for, evidence supporting the hypothesis evaporates.

Despite the controversy, virtually all economists agree on one point: More information regarding job hazards would help “the market” generate compensating wages. One idea would require firms to include hazard information and fatality rates on job application forms the same way food manufacturers list fat content on packaged food.

WALL STREET  

Wall Street refers to the geographical concentration of financial service providers that constitutes New York’s financial district. Its heart is the narrow thoroughfare of the same name in Lower Manhattan that is home to the New York Stock Exchange. The term carries a wide spectrum of meanings that intersect geography, finance, and political economy.

The origins of Wall Street can be traced to the brushwood barricade erected by Peter Stuyvesant along the northern boundary of the New Amsterdam community of Dutch settlers in Lower Manhattan in 1653. The “wall” was meant to protect the early settlers against attack from Lenape Indians, New England colonists, and the British (who dismantled it in 1699). The subsequent growth and lore of local merchants and financiers imbued this simple geographic setting with its modern significance—the story of the formation of a world financial center, the powerful headquarters of U.S. financial capital.

THE RISE OF A FINANCIAL CENTER: Finance and Geography  

Wall Street’s early history as a financial market began with gatherings of securities and commodities traders during the Revolutionary War. These curbstone and coffeehouse traders first developed financial techniques for loans and shares out of the needs of mercantile trade, a rudimentary copy of the 1600s Dutch exchanges. The consolidation of the New York exchange accelerated with U.S. government demands for new sources of capital to bail out securities issued to finance the Revolutionary War. The first Continental Congresses in New York issued $80 million in government bonds under Alexander Hamilton to redeem war debts at face value. Speculators seeking to profit on leaked news of the bailout plan set up operations at the east end of the street to broker insider trading of the government paper.

Wall Street’s development during the eighteenth century was shaped by trade in government debt and state-licensed monopolies. During the nineteenth century, railroad shares and bonds fueled the market and its proliferation of trading instruments. Early institutional development was characterized by the monopolization of trading activity that excluded informal curb participants and curtailed the growth of rival exchanges. On May 17, 1792, twenty-four stockbrokers signed the “Buttonwood Agreement” (so named for the sycamore tree on Wall Street under which the signing is said to have taken place). The accord restricted membership and formalized rules for the loosely associated “Brokers for the Purchase and Sale of Public Stock” who conducted their exchange auctions out of the Tontine Coffee House. The financial turbulence of the War of 1812 prompted creation of the New York Stock and Exchange Board (NYSEB) in 1817. The board turned a handsome profit by financing the Erie Canal. It further restricted membership, enforced full commissions and secrecy, and moved member brokers into rented office space. The measures served to snuff out competition from rival curbstone exchanges, such as the 1835 Commercial Exchange Association.

The 1840s to the 1860s produced growth in securities issues associated with railroad stock (first listed in 1830). A major speculative boom driven by Civil War finance (1861–1865) spawned demand for new manufacture and mining and a swelling trade in government debt. This activity fueled persistent attempts to establish rival exchanges to the NYSEB, which culminated in the formation of the Open Regular Board in 1864. Unable to remove the Open Board from the trading arena, the NYSEB was forced to merge with it in 1869. This merger created the New York Stock Exchange as it is now known, with its 1,060 founding members. Subsequent challenges by rival exchanges, such as the Consolidated Stock and Petroleum Exchange (CSPE) founded in 1885, provoked aggressive response by the NYSE, which outlawed CSPE dealings and in 1900 ordered Western Union to stop supplying quotation services to all rival exchanges in New York City (Doede 1967, p. 14).

Financial turbulence in conjunction with the growing concentration of wealth on Wall Street prompted congressional reaction with the Pujo hearings in 1907. Wall Street was implicated in the monopolistic practices of the money trusts that facilitated industrial concentration under the control of a small number of corporations. During the
1920s, Wall Street flourished as a financial center, promoting the rise of large corporations with dispersed ownership and professional management along with a dramatic concentration of capital.

The fragile foundation of this accumulation of financial claims became apparent with the Black Thursday stock market crash of October 24, 1929, and the Black Tuesday sell-off panic that began on October 29. The collapse in equity prices came at the height of Wall Street’s reputation and prompted a wave of regulatory legislation, from the 1933 Bank Act to the creation of the Securities and Exchange Commission in 1934. In the world of finance, Wall Street’s characteristic business activity had produced a speculative financial frenzy that put short-term capital gains before enterprise, setting the stage for a debt-deflation crisis that brought down more than nine thousand banks and triggered the onset of the Great Depression in the 1930s. From this historical episode, major debates ensued about the role of financial markets in the development process.

Viewed from the perspective of the efficient markets hypothesis, Wall Street is the archetype of a highly competitive, efficient capital market whose prices reflect all relevant information. It is impossible to beat the market, and capital is optimally allocated to productive firms. Viewed from the financial instability school of thought, however, Wall Street is predisposed to speculative excess, where the larger constellation of private credit-creating institutions serve the interests of financial accumulation, distorting the allocation of productive capital in debilitating waves of crisis and bankruptcy. Contemporary reference to the “Wall Street View,” coined by Hyman Minsky, derives from this interpretation of the Great Depression’s speculative overleveraging and collapse in world capital markets. Laissez-faire finance, absent regulation and supervision, produces destabilizing real economic performance.

Throughout the 1930s Wall Street exchanges shrank from losses. Trading during the post–World War II golden age was lackluster until the end of the 1950s. In perspective, NYSE trading for all of 1950 was 525 million shares, which was equivalent to just two hours of an average day’s trading volume in 2005. Wall Street emerged by securing its geographic and financial monopoly over U.S. capital markets. The dense area of real estate demarked by Wall and Broad Streets came to include the New York and American stock exchanges, member firms, over-the-counter firms, government securities dealers, major banks and trust companies, the New York Federal Reserve Bank, and countless insurance, utility, mercantile, and commodity exchanges. The NYSE became the symbolic hub for U.S. financial capital. The amount of new capital Wall Street actually provisioned for “Main Street,” however, proved to be quite low—less than 1 percent of gross domestic product (GDP). It is not new capital but retrading existing capital that defines Wall Street’s key development role. Following the 1970s, speculative financial leveraging of accumulation returned to Wall Street, exploding trading volumes, where the banking system was engaged to secure profits on capital gains from asset price run-ups on financial claims. The resulting market volatility made more observers receptive to the financial instability hypothesis.

**THE POLITICAL ECONOMY OF FINANCE CAPITAL**

In the world of political economy, Wall Street signifies the epicenter of U.S. and global financial capital. In the tradition of imperialist extension, Wall Street is seen as having the power to create or undermine nations in accordance with U.S. national interest. Wall Street speculators, most notably J. P. Morgan, played a decisive role in Panama’s secession from Colombia and its birth as a nation in 1903 to ensure huge profits from the construction of the Panama Canal and U.S. controlling interest in the Canal Zone (Díaz Espinoza 2001). Morgan’s Wall Street partnership bought up the worthless stock of the failed French Canal Company in 1900 and dispatched Nelson Cromwell to convince the U.S. government to purchase the company’s rights and equipment at an exorbitant price. When Colombia’s refusal to ratify the Hay–Herran Treaty threatened Washington’s rights to build the canal, Wall Street financiers funded an uprising by Panamanian nationalists, causing President Theodore Roosevelt to deploy U.S. troops to the region.

Nineteenth-century political critique faulted Wall Street for advancing the monopoly powers of national capital and imperialist extension. Modern variants of this viewpoint examine in greater detail the evolving technology of financial institutions in promoting “accumulation by dispossession” (Harvey 2003, p. 147), where predatory asset redistributions are produced in the context of speculation-induced economic crises. Attention concentrates on the wave of financialization that occurred after 1973. Transactions involved stock promotions, Ponzi schemes, international debt-pushing and repayment servitude alongside speculative raiding conducted by hedge funds. The global reach of Wall Street’s agenda and contribution to financial instability is captured in the reference to the “Wall Street–Treasury–IMF complex.” This highlights the desire of large brokerage firms to have access to capital markets throughout the world through enforcement of complete capital account convertibility, while the International Monetary Fund (IMF) asserts its role as an international lender of last resort in the wake of impending crises.
The destruction of Manhattan’s World Trade Towers on September 11, 2001, made evident that Wall Street’s financial nexus had assumed symbolic dimensions as the center of U.S. financial power and was vulnerable to attack. A previous episode had occurred on September 6, 1920, when a bomb was exploded outside the NYSE building, killing thirty-three people. The post 9/11 geography of money produced a diaspora of the financial industry out of its concentrated center in Lower Manhattan. The disaster dislocated fifty thousand financial service employees to new office space in Midtown Manhattan and nineteen thousand across the river to New Jersey. Over thirteen million square feet of class A office space were completely destroyed, and insurance industry claims from property and life topped $40 billion.

Wall Street’s financial dominance continues despite encroaching competition by rival exchanges trading with new electronic technologies. In 2006 the NYSE acquired Archipelago Holdings, a rival exchange based entirely on electronically traded funds. The resultant public corporation, NYSE Group, took on the all-electronic NASDAQ to consolidate its control in the Internet trading world, where member “seats” and “trading floor” no longer signify geographic reference when accounting for revenue streams. The NYSE Group’s subsequent merger with Euronext produced the first transatlantic bourse.

Joseph Ricciardi

WALLERSTEIN, IMMANUEL 1930–

Immanuel Wallerstein has been one of the most influential and prolific American sociologists in the post–World War II (1939–1945) period. He obtained his B.A. (1951), M.A. (1954), and PhD (1959) from Columbia University in New York City. In his early years as an assistant professor of sociology there, Wallerstein was primarily a political sociologist. His expertise in Africa’s independence movements led to his meeting social theorist Frantz Fanon (1925–1961) while doing fieldwork in the region. The political and revolutionary activity sweeping the African continent in the late 1950s and early 1960s caused Wallerstein to question the traditional focus on the nation-state as a meaningful unit of analysis, particularly in those areas of the world where such entities were an obvious byproduct of prolonged colonialism and imperialism. In the late 1960s, Wallerstein politically sided with students in their anti–Vietnam War (1957–1975) protests against university administrators, a confrontation that resulted in his book University in Turmoil (1969) and his decision to leave Columbia to join the Department of Sociology at McGill University in Montreal. It was during his tenure there, and inspired by French economic historian Fernand Braudel’s (1902–1985) long-term vision of historical processes, that he published the first volume of The Modern World-System (1974), which has been translated into thirteen languages. In combination with Volume 2 (1980) and Volume 3 (1989), the trilogy has had a significant impact in the fields of sociology, political economy, history, geography, and more recently, anthropology and comparative literature.

Wallerstein’s main thesis in these and other studies is that capitalism is a specific socioeconomic system, characterized by an axial division of labor resulting from intense yet unequal bulk trade linkages between different zones, which he labeled the core, periphery, and semiperiphery. This capitalist world-system emerged in sixteenth-century Europe and subsequently expanded to incorporate more
areas (e.g., various minisystems and world empires not characterized by the same primacy of ceaseless capital accumulation). In the context of the colonialism and imperialism that unfolded from 1492 until the early twentieth century, the entire world became interlinked through these trade patterns constitutive of unequal exchange. The latter was also a major concern of the Latin American dependency school, which in the 1960s argued that the unequal power relationships reproduced through world trade mechanisms in the context of imperialism were the result of the relationship between metropolis and periphery. By stressing the importance of economic cycles and the commodity chains of leading sectors, however, Wallerstein espoused the idea that the upward and downward social mobility of specific polities was possible (as demonstrated, for example, by Spain, South Korea, and Taiwan).

Wallerstein also argued against the modernization or developmentalist school, dominant in the 1960s, which assumed that every country could achieve upward social mobility as long as it implemented the correct policies. For Wallerstein, the growth of world trade does not alter the fact that it is essentially a polarizing zero-sum game, reproducing and expanding poverty and inequality on a world scale. The crucial Wallersteinian concept of semiperiphery was introduced to clarify this idea theoretically: the three zones in which different political entities (nation-states, principalities, etc.) are located contain divergent practices (in terms of life expectancy, standard of living, labor control, production of items for sale on the world market, and political regimes) precisely because of their hierarchical location within the capitalist world-economy.

Unlike the orthodox Marxists’ focus on the nation-state, Wallerstein and other world-system analysts (e.g., Samir Amin) conceptually regard free labor and slavery as coexisting within the same mode of production. Using the world-economy as the sole unit of analysis, Wallerstein insists that labor control and production for trade are historically, relationally, and therefore mutually constitutive: only because wage remuneration in the periphery, which mostly exports raw materials for the world market, is so low, is wage remuneration so relatively high in the core, where value-added products are exported.

After joining the Sociology Department at the State University of New York at Binghamton, Wallerstein created the Fernand Braudel Center for the Study of Economies, Historical Systems, and Civilizations in 1976 and its scholarly journal, Review. There he systematically wrote on cycles and trends of the world-economy, commodity chains, hegemony, antisystemic movements, households, racism and sexism, and the geoculture from a world-system perspective. One key historical event was the 1848 world revolution, in which spontaneous antisystemic (especially socialist and nationalist) movements organized themselves politically in order to obtain state power. Their eventual success in turn led to the 1968 world revolution, engineered by different antisystemic movements from the New Left. Wallerstein claims that 1968 put an end to faith in universal progress and related classical liberal paradigms, which coincided with the beginning of American decline because of its loss of significant economic superiority to Western Europe and Japan and its political-military defeat in Vietnam.

Beginning in the 1980s, Wallerstein argued that the United States was from 1945 onward in de facto collusion with the Soviet Union, and he characterized the latter not as a communist experiment but as a typical powerful semiperipheral state that embraced protectionism (as opposed to the typical state located in the core in favor of free trade). Similarly, World War I (1914–1918) and World War II are interpreted as one major war to determine which state would succeed England as hegemon, the primus inter pares in the core zone that temporarily benefits from unprecedented financial, political, and ideological capital. From the late 1980s onward, Wallerstein predicted ever more crisis in the world-system due to a gradually falling rate of profit linked to increasing pressures from antisystemic movements, environmental constraints, democratization, and wage increases concurrent with urbanization. In this period he agreed with most of the studies written by his colleague, Andre Gunder Frank. But in the early 1990s, Frank, who was attempting to trace world-system economic cycles to as far back as 500 BCE, began to criticize his former collaborator as being Eurocentrist. He also argued, contra Wallerstein, that the modern world-system was not so much in terminal crisis as experiencing yet another transition towards East Asian hegemony.

Starting in the 1990s, Wallerstein’s writings focused more on the changing geoculture of the modern world-system. Since his term as president of the International Sociological Association (1994–1998), his scholarly contributions have been particularly geared towards unthinking nineteenth-century paradigms and critically reflecting upon the structures of knowledge production in the academic realm of the world-system. These efforts are best illustrated by his chairing of the Gulbenkian Commission on the Restructuring of the Social Sciences (1993–1995) and his publishing of The End of the World as We Know It (1999) and The Uncertainties of Knowledge (2004). Not unlike the later years of sociologist Pierre Bourdieu (1930–2002), Wallerstein’s increased scholarly recognition—reflected in his move to Yale University in 2000—coincided with an increasing engagement in the political field. Evidence of this can be found in his public interventions at the World Social Forum with regard to potential strategies that progressive movements may consider (see
Utopistics [1998]) and in his desire to engage with a broader audience through public lectures and various biweekly commentaries (posted on the Internet as of October 1998). One of his lasting contributions has been the creation of the Political Economy of the World System Section of the American Sociological Association, which has continually increased its membership over the years and for which he is often the keynote speaker.

WALRAS, LÉON

1834–1910

Marie Ésprit Walras was born on December 16, 1834, in Évreux (Upper Normandy, France) to Auguste (1801–1866) and Louise-Aline Sainte-Beuve (1811–1893). Despite having no university degree, Léon Walras was offered a professorship at the University of Lausanne on November 12, 1870. He officially occupied the chair of political economy from October 20, 1871 to 1892, when he retired early for health reasons. His political and social economy is best examined through the trilogy of works titled Éléments d’économie politique pure (Elements of Pure Economics or the Theory of Social Wealth, 1874–1877, 1889, 1896, 1900), Études d’économie sociale (Studies in Social Economics or the Theory of Distribution of Social Wealth, 1896), and Études d’économie politique appliquée (Studies in Applied Economics or the Theory of Production of Social Wealth, 1898). Walras died at his home in Clarens (Vaud, Switzerland) on January 5, 1910.

Founder of the School of Lausanne, Walras is one of the economists whose contributions have decisively influenced the development of economic theory. Almost simultaneously with, but independently from, Carl Menger (1840–1921) and Stanley Jevons (1835–1882), Walras introduced the concept of marginal utility (rareté) and took an important step toward the mathematization of economics. In his view, mathematics is not only one of the possible forms of expressing economics but also is the form necessarily required for a rigorous formulation of economic laws.

However, Walras’s most original and important contribution is the analysis of price determination by means of the interactions between the various markets that make up an economy. The modern analysis of the existence, uniqueness, and stability of general equilibrium had been inspired by Walras’s Pure Economics. In the 1950s modern theorists, with the use of advanced mathematics, specified the hypotheses enabling them to rigorously prove the existence of a price system equalizing supply and demand on each market—that is, the existence of a general equilibrium. In this perspective, the Walrasian tâtonnement (groping) was interpreted as a process of convergence of prices towards equilibrium, a representation of how markets actually work. Nevertheless, in the early 1970s enthusiasm chilled. It was proven that in a general equilibrium framework aggregate excess demand functions have an arbitrary nature, while specific assumption must be made to obtain uniqueness and stability results. To simplify matters rather drastically, as every change in the price system affects one’s income and purchasing power, the aggregate excess demand functions that result behave capriciously. In others words, income effects prevent the groping process from leading to equilibrium. So, the correspondence between the hypothesis of the homo oeconomicus and the convergence towards equilibrium does not hold, and the tâtonnement process cannot be interpreted as the process that allows economic equilibrium to be reached.

Modern developments of general equilibrium have been inspired by Walras’s theory of value in exchange (pure economics), while his theories of production and distribution of social wealth (applied and social economics) have been neglected. But from the perspective of the history of economic thought it is not possible to assert that pure economics is separable from the other two parts of the Walrasian triptych (applied economics and social economics) or that pure economics only is worthy of scientific consideration. Thanks to the publication of Walras’s collected writings (1987–2005), historians of economic thought now rarely discuss Walras’s works referring only
to pure economics, even though there is still no consensus on the relationships between these three components of Walras’s political and social economy.

Nevertheless, the actual and fundamental controversy about Walras’s writings involves the meaning of general equilibrium theory and what it is supposed to refer to. Most scholars considered Walras’s general equilibrium theory as an attempt to represent the actual working of nineteenth-century capitalism, even though they disagreed on its heuristic value. For most critics, the general equilibrium theory is simply inadequate for this task, both in Walras’s and in modern versions. Others instead find in Walras’s writing some elements pertinent for the understanding of real markets. Finally, some argue that one can learn more from the differences between model and reality than from their alleged similarities.

However, if one takes Walras’s philosophy of science seriously, a different point of view emerges: general equilibrium does not refer to actual market working or other economic facts but to the social wealth considered in itself. Pure economics does not aim at representing, in a more or less faithful and simplified manner, the contingent reality but rather at grasping the essence of the reality which does not yet completely exist, a reality in its becoming. For Walras, general equilibrium is the perfect, ideal form, towards which economic systems are evolving but are not yet realized. This ideal form is described in Walras’s *Elements of Pure Economics*, but in his other writings he often referred to the economic and social phenomena that were right before his eyes: one might cite the essays on money and credit, monopolies, and railroads, but also on salaries, tax system, and real estate. These studies are definitely far from being an apology of the market as a self-driven and self-regulating mechanism. Instead, they represent a long list of cases requiring State intervention. The State has to organize the economy in order to approach the ideal form represented by general equilibrium but it is also destined to produce as a monopolist where too much competition kills competition.

Finally, three different Léon Walras have to be considered. The first is a neoclassical icon, the founder of neowalrasian economics, but known by economists at best as the author of *Elements of Pure Economics* only. The second is the founder of the School of Lausanne and the father of general equilibrium as a formalized invisible hand. The third, unknown to economists and only recently discovered by historians of thought, is a critic not only of the capitalism of his time, but of market economy in itself.

**WALRAS’ LAW**

Walras’ law is a powerful modeling tool that is used by economists when they undertake general equilibrium analysis. It captures the interdependence between markets implied by the budgetary constraint that all individual transactors (i.e., a single person, a household, a firm, or the government) must take into account when they formulate purchase and sales plans.

It is assumed that no individual transactor in a market economy is so misguided as to suppose that he or she can acquire something for nothing. This being the case, the plan to purchase (or sell) something necessarily implies the plan to sell (or purchase) something of equal value. In the language of economics, each individual must satisfy his or her budget constraint. Consequently, for each individual the total value of the planned supply must exactly equal the total value of the planned demand. This means that there can be neither an excess of demand over supply (excess demand) nor an excess of supply over demand (excess supply) at the level of the individual.

It follows by simple aggregation that there can be no excess demand or excess supply in the aggregate whether one is summing over the individuals as individuals or as participants in various markets, and this must be true whether or not prevailing market prices are such as to equate demand with supply for each specific commodity. In other words, the aggregate market value of supply equals the aggregate market value of demand for any set of prices, not just the equilibrium set of prices. This proposition sometimes is called Walras’ law but more commonly is known as Walras’ identity.

Walras’ identity implies that if there is ever an excess of demand over supply for any single commodity, there must be a corresponding excess of supply over demand for at least one other commodity; otherwise the aggregate value of commodities that agents wish to supply could not be equal to the aggregate value of commodities that agents wish to demand. Another way to put this is to say that the aggregate value of the excess demands and the excess supplies over all the markets must equal zero and that this applies whether or not all the markets are in equilibrium.
This proposition is one of a number of logical implications of Walras’ identity that is given the name Walras’ law. Léon Walras explicitly formulated and drew upon this proposition in his attempt to explain how general economic equilibrium may be established in a market economy (Walras [1926] 1954).

Walras’ law is a statement that refers to all markets taken together (that is, it refers to the aggregation of the markets for final goods and services along with the markets for raw materials, labor, money, and bonds) and should not be confused with a proposition known as Say’s law, or at least one version of it (Sowell 1972), which claims that there never can be an excess supply of final goods and services taken alone. Although Walras’ law asserts the logical impossibility of oversupply in all markets taken together, it does not rule out the possibility of there being an oversupply in a particular market, such as the market for final goods and services, taken alone.

Walras’ identity and Walras’ law are valid whether or not market prices equate demand with supply for each and every commodity, and because of this they have implications for both equilibrium and disequilibrium situations. Those implications are of such fundamental importance in modeling interdependence between markets that they often have been used by writers to define Walras’ law.

Equilibrium in a market is a situation in which the price of the commodity is such that the supply of the commodity is equal to the demand for it. Now, suppose a set of prices has been established that will equate demand with supply in every market except the n-th market. Because there can be neither excess supply nor excess demand in the aggregate, it follows that if all but one of the markets in an economy are in equilibrium, that other market also must be in equilibrium. Thus, to demonstrate that a situation of general equilibrium holds, it suffices to show that n – 1 markets are in equilibrium. This implication of Walras’ law plays an important role in models of markets and models of asset portfolios.

In regard to the implications of Walras’ law for disequilibrium, the law implies that regardless of the price that is set, the aggregate value of excess demands in the system equals the aggregate value of excess supplies. This carries the implication that an excess supply in any one market must be matched by an equal value of excess demand in some other market or markets. To put this statement slightly differently, if there is a disequilibrium in any one market, at least one other market must also be in disequilibrium.

This implication of Walras’ law leads many to be concerned about the theoretical grounding of John Maynard Keynes’s theory of unemployment, which seems to suggest that the labor market can be in disequilibrium even if all other markets are in equilibrium. An important contribution to this debate was made in 1965 by Robert Clower, who pointed out that in Walrasian analysis the excess demands and supplies are measured as differences between planned or “notional” demands and supplies, not between actual or “effective” demands and supplies. Clower suggested that Walrasian analysis is not appropriate for modeling situations in which there is involuntary unemployment (an excess supply of labor) because this excess supply in the labor market will result in household incomes that are lower than what the households were counting on when they formulated their expenditure plans. As a result the excess supply in the labor market will be matched by only a notional and not an effective excess demand for commodities.

Although in this situation certain prices will be at disequilibrium levels, no process of bidding them away from those inappropriate levels may get started, and so it can be argued that unemployment persists because the market signals that are presupposed in much general equilibrium analysis are not transmitted. Consideration of issues such as these has led to the development of non-Walrasian approaches to economics. In particular, in 1971 and 1976 Robert Barro and Herschel Grossman formalized the ideas of Clower and others and laid the foundations for a non-Walrasian macroeconomics.

Robert Dixon
WALTZ, KENNETH
1924–

Kenneth Neal Waltz, born and raised in Ann Arbor, Michigan, is best known for developing the neorealist or structural realist approach to the study of international relations. A central figure in the development of international relations scholarship in the post–World War II (1939–1945) era, Waltz has also made notable contributions to the understanding of nuclear weapons proliferation and its consequences. Waltz received his bachelor’s degree from Oberlin College in 1948 and his graduate degrees from Columbia University in the 1950s. He retired from teaching in the mid-1990s and, as of 2005, was serving as Emeritus Ford Professor of Political Science at the University of California at Berkeley and as an adjunct professor of political science at Columbia University.

Waltz’s earliest contribution, presented in Man, the State, and War: A Theoretical Analysis (1954), organizes the primary causes of war into three distinct images or levels of analysis. The first image considers human nature and whether it can be developed and constrained in such a way as to minimize the likelihood of war. The second image emphasizes domestic political factors as the source of interstate conflicts. Finally, the third image identifies as the key causes of war the structure of the international system and, in particular, the absence of any centralized arbiter to settle disputes among countries, a condition known in international relations as anarchy. Through these levels of analysis, Waltz seeks to isolate and therefore better understand the root causes of conflict among countries.

Waltz’s most influential work is Theory of International Politics (1979), in which he elaborates the principal tenets and predictions of neorealism. Sometimes called structural realism, neorealism emphasizes third-level causes of conflict among countries. As a result of anarchy, states can trust only themselves to secure their survival. Therefore, they must always be suspicious of others, making cooperation with other countries limited and infrequent. In Waltz’s view, even though states must strive for security, they do not intrinsically seek boundless power or territory; therefore, once their security needs are met, most states will accept the status quo and avoid conflict with other states. States whose ambitions exceed these legitimate security needs can be contained by the systemic balance of power.

Beginning in the 1980s, Waltz’s research turned increasingly to the implications of nuclear proliferation. The leading nuclear optimist, Waltz argues that, given the destruction any nuclear exchange would entail, an increase in the number of states with nuclear weapons makes the international system more stable and armed conflict less likely. In effect, nuclear proliferation obligates states to be more restrained and careful in their relations with other countries. Nuclear pessimists, on the other hand, contend that the proliferation of nuclear weapons destabilizes international relations. Together with Scott D. Sagan, Waltz coauthored The Spread of Nuclear Weapons: A Debate (1995), which elaborates the debate between nuclear pessimists and optimists in the context of the cold war’s superpower nuclear standoff. Sagan and Waltz reissued their book in 2002 with an expanded discussion of proliferation in India and Pakistan, and of the threat of nuclear weapons being acquired by terrorists.

WANT CREATION

Introductory economics textbooks assume consumers are sovereign in the market. The preferences of consumers are supposed to be authentic, self-generated. Consumers’ preferences are supposed to determine what producers supply. But this is an age in which producers increasingly contest that sovereignty. With powerful corporations, costly information, pervasive advertising, and persuasive salesmanship, consumers are less independent, their preferences less authentic. Created wants do not arise spontaneously from individual preferences but from advertising and salesmanship. John Kenneth Galbraith described such want creation as “the revised sequence” (Galbraith 1967, p. 212).

Of course, the traditionally accepted sequence still operates. Information about what is wanted still flows from consumers to producers, from the demand side of the product market to the supply side. Not all wants are created by producers. Sovereign consumers have not lost their power. But they do have to share it. Producers no longer respond passively to consumer whim, if they ever wholly did. The sovereignty of the consumer is being challenged on a widening front. A significant flow of information is now going in the other direction. A revised sequence has been established in which information flows from producer to consumer, from the supply side of the product market to the demand side. Supply has begun to create demand. Consumer wants have begun to depend
on producer production. Galbraith coined the phrase “the dependence effect” to describe consumption that depends on production (Galbraith, 1969, p. 143).

THE SIGNIFICANCE OF WANT CREATION

Want creation reduces the authenticity and the urgency of consumer preferences. It undermines much of neoclassical economics. It cuts the hearts out of microeconomic and welfare theory, changes macroeconomic theory, and forces a reconsideration of the benefits of globalization. If taken seriously, want creation would revolutionize textbook economics, where it is still largely ignored.

In microeconomic theory, want creation means that the price mechanism is not the only way markets reach equilibrium. Excess supply of consumer goods may or may not be eliminated by a decline in the market price. It may also be eliminated by an increase in advertising and salesmanship and other alterations in the flow of information from producer to consumer—all intended to shift the demand curve to the right instead of moving downward along the demand curve toward a lower price and higher quantity demanded. Excess demand for consumer goods, likewise but in reverse, may or may not be eliminated by the price mechanism. That is, advertising, salesmanship, and information management may be adjusted downward, instead of price being adjusted upward, to clear the excess demand from the market. Want creation introduces indeterminacy and producer discretion into the market adjustment process (Waller and Robertson 1998).

In welfare theory, want creation destroys the presumption of market optimality. To the extent that wants are created so that producers can profit by supplying them, equilibrium in the product market does not represent optimal consumer utility in the form of consumer surplus. In fact, consumer surplus loses its meaning when consumer wants are created by producers. Furthermore, if workers supply their work in order to buy the products that meet the wants created by the producers who hire them, how can it be said that human welfare is served?

In macroeconomic theory, want creation replaces more orthodox consumption functions with the demonstration effect (Duesenberry 1949). When the desirability of new goods and services is demonstrated to consumers, short-run consumption permanently shifts up to include the new item. This makes the average and marginal propensities to consume the same in the long run, even if the marginal propensity is less than the average propensity in the short run. Of course, in the United States, want creation has made the pressure to consume so intense that the marginal and average propensities are both close to unity.

When wants are created, it is questionable to what extent underdeveloped countries benefit from globalization when it opens them up to the advertising, salesmanship, and information management exercised by the powerful corporations of developed countries (Dugger 1998).

Applied to a wide range of economic doctrines, want creation is a subversive concept.

Among the economists seriously discussing want creation are Robert H. Frank, who is linking individual preferences to social emulation (Frank 1985, 1999), and Juliet B. Schor, whose work is more focused on manipulation by advertisers (Schor 1991, 1998).

WANTS

In economics, the term want refers to a wish or desire to own goods and services that give satisfaction. More generally, the concept involves the endless succession of material wants exhibited by all human beings. Material wants are the desires of consumers to obtain and use various goods and services that provide utility. Usually, wants are backed by effective demand—ability and willingness to pay.
Wants

Nature has made lavish the distribution of its natural resources and this has brought about an endless desire for many things even though they may not necessarily be basic needs (food, clothing, and shelter). As basic needs and wants are satisfied, other wants will arise. For this reason, human wants are unlimited: The satisfaction of one want leads to another. At the same time, the means (natural, human, and manufactured) used in satisfying them are limited (scarce).

The study of economics begins with a consideration of scarcity. Scarcity refers to a situation in which goods and services are limited in supply, and thus the full demand for those goods and services cannot be met. Because people have unlimited wants—and thus want more than they have or can purchase with their incomes—what they have is never enough, even if they are wealthy. And given that people do not have everything they want, they must use their limited time and income to select those things they want most and forgo the rest. The choices they make and the manner in which the choices are made explain much of why the real world is what it is. A choice is simply a comparison of alternatives. When you choose one thing, the lost benefits of the next best alternative represent the opportunity cost of your choice.

The rapid introduction of new products whets our appetites and extensive advertising persuades us that we need countless items we might not otherwise buy. For instance, not too long ago, we did not want light beer, videocassette recorders, fax machines, or compact discs—because they did not exist. The overall objective of all economic activity is to attempt to satisfy material wants, both longstanding and newly created.

The wants of consumers (goods and services) become available through business activities. It is, then, business that produces the food, clothing, shelter, furniture, household utensils, and so on that we all need. It supplies us with all our means of transportation, from the simple bicycle to the sophisticated airliner. It provides all our entertainment, from children's comics to the television programs beamed to us from satellites in space.

Wants expressed as effective demand reflect major economic decisions by states, corporate institutions, and multilateral institutions, and are significantly affected by forces emanating from either the world market or domestic markets. For instance, domestic pricing mechanisms influence the investment decisions of individuals, as well as corporate economic factors. Examples can be found in the stock exchange process, in which decisions to buy or sell stocks are influenced by stock values.

In practical terms, wants for goods emanate from consumers, and thus producers produce what consumers need; if they do not, they may go out of business. Furthermore, if production is undertaken in order to sup-

ply the wants of mankind, then demand must be the basic
force in economics. Every individual demands goods and services and when all the individual demands are put together, the resulting composite demand is what industry must meet if people are to achieve satisfaction. Demand for goods that are not to our personal taste, or are less fashionable or less well promoted through advertisement will be weaker. Tastes and preferences, as well as publicity, thus play some part in determining the total want for a commodity or service.

At the national level, the overall want of countries may differ, depending on their level of development (technological, human, and material), income, state of peace or war, and natural resources. For example, a war-torn country will have a constant need to import arms. Because nature has not equitably distributed its resources over the surface of the earth, nation-states depend on one another for those goods for which they have the least comparative cost advantage. The exchange between nations of such resources is an obvious solution to national shortages.

Nations may have diverse wants (perhaps reflected in development programs and projects), but few resources. This scarcity of resources comprises a huge constraint, and thus nations may be forced to drop some of their white elephant projects and arrange their programs in order of importance pending the availability of funds. With scarcity, which ensures that nations' wants exceed what they can actually produce, potential demand will obviously exceed potential supply. As a result, the shortfall in supply of a nation's wants will be made up by other nations.

More significantly, national wants determine the level of international trade and what categories of goods (wants) will be imported. For instance, for years the United States stockpiled its own oil resources for strategic reasons and instead used cheap supplies from Venezuela and the Middle East. Similarly, Great Britain has allowed its own cotton industry to run down in the face of competition from the newly industrialized countries of the Far East, whose cheap labor and skillful exploitation of new technology have made them more economical than Lancashire. This economic philosophy of wants has been criticized for being excessively laissez-faire.

Wants are driven by self-interest, and in most cases involve a clash of interests. For example, nations may go to war to protect their own "national interest" despite the obvious consequences. Another difficulty connected with the satisfaction of human wants is that people and nations are spread around the world in a very haphazard way, making it impossible to evenly satisfy human wants; furthermore, one person's wants may be another person's needs and vice versa. In addition, the means of fulfilling wants are inherently limited, as the world at any given
time can only produce a limited amount of goods and services due to the limited resources at its disposal.

Wants as an economic desire never cease; they grow in spiral-like movements of business activity. We engage in business activity so that we can satisfy human wants. When we do satisfy these wants, the very act of satisfaction consumes the useful goods or services created and we must start the process again in order to supply a further batch. The process goes from wants through enterprise, production, distribution, and marketing to consumption and satisfaction, and back to wants again.

WAR

In general, war is the outbreak of armed hostilities within, between, or among states or other political groups and communities, in which strategic, political, economic, and other important outcomes are decided mainly by the use of military force. In international law, war is a legal condition of open and declared hostility between or among states, wherein diplomatic relations are automatically severed (if an official state of war is declared) and states may use any military force deemed appropriate or effective, subject only to the laws of war and perhaps to notions of “just war.” According to the Bismarckian reallpolitik (“realistic politics”) school of international relations, war as organized political violence is the ultimate “self-help” device in the power politics of an anarchic world consisting of sovereign states. The “Iron Chancellor” Otto von Bismarck (1815–1898), architect of Germany’s “reunification from above” during the nineteenth century, recognized the importance of war’s nation-building function, declaring in the German Bundestag that “It is not by speeches and resolutions that the great questions of the time are decided … but by iron and blood” (Barash and Webl 2002, p. 58).

According to the most illustrious “philosopher of war,” Carl von Clausewitz, a nineteenth-century Prussian army officer best known for his treatise On War, war is “not a mere act of policy, but a true political instrument, a continuation of political activity by other means” (Clausewitz [1832] 1976, p. 87). In other words, war is fundamentally a continuation of a country’s peacetime diplomacy by other, more violent methods, rather than a complete break with it. It is not an act of senseless fury and violence, but an orchestrated military action with a particular strategic goal in mind—namely, disarming one’s opponents to the point where they cannot resist one’s demands. This conception of warfare as essentially political in nature is in accord with Clausewitz’s general definition of war as “an act of force to compel the enemy to do our will.” War, he wrote, is “nothing but a duel on a larger scale” ([1832] 1976, p. 75). In contrast, Marxist and neo-Marxist writers emphasize the socioeconomic causes of war, claiming that mankind has been historically in a state of almost perpetual warfare due to the economic interests of the dominant social classes. Since the rise of class-divided society in the Early Bronze Age (c. 3500–2000 B.C.E.), war has been promoted by powerful members of the socially dominant classes who are seeking—out of sheer economic self-interest or imperialist ambition—to gain colonies, export markets, or natural resources abroad; political and economic spheres of influence; regional or global domination; and so on. The American Socialist leader Eugene Debs (1855–1926) told an antiwar rally in 1917: “Wars throughout history have been waged for conquest and plunder…. The master class has always declared the wars; the subject class has always fought the battles” (Zinn 2005, p. 27).

Quincy Wright (1890–1970), a pioneering peace and conflict researcher, considered a war to have taken place either when it was formally declared or when a certain number of troops—at least 50,000 as a minimum—were involved. Other writers have defined wars by the number of deaths incurred, focusing on a minimum of 1,000 combat-related fatalities—either per war or per year of the conflict (see Singer and Small 1972; Eckhardt 1991). Reality is, of course, much more complicated than such definitions of war. In the War of the Bavarian Succession (1778–1779), for instance, after an official state of war had been declared, the Prussian and Austrian armies marched against each other in the field, but not a single shot was fired in anger and, as a result, no one died. In contrast, during the Korean War (1950–1953), in which nearly 3 million people—mostly innocent civilians—were
killed, including more than 54,000 Americans, there was neither an official declaration of war nor the signing of a peace treaty, and the whole conflict was euphemistically labeled a “U.N. police action.” In the First Gulf War (1990–1991), not only was an official state of war never declared, nor a peace treaty signed at the end of the hostilities, but diplomatic relations with Iraq were not severed by most of its adversaries.

The sheer wastefulness of warfare in terms of human, economic, environmental, and social losses has been appalling, even without the use of nuclear weapons. For example, during the Thirty Years’ War (1618–1648) a third of Germany’s population was killed. At least 9 million soldiers and more than 1 million civilians died during World War I (1914–1918), with approximately 20 million more people perishing during the war-driven influenza epidemic of 1918. During the Battle of the Sommes in 1916, the joint British-French forces tried for five months to break through German lines, gaining a mere 120 square miles at a cost of 420,000 British and nearly 200,000 French soldiers; the Germans lost 445,000. Military deaths in World War II (1939–1945), during which nuclear bombs were dropped on the Japanese cities of Hiroshima and Nagasaki, were about 17 million, but civilian deaths—at approximately 35 million—were many times greater than in World War I. Of the 2.9 million Americans who served in the military during the undeclared Vietnam War, more than 58,000 were killed, 3,000 became missing in action, and more than 300,000 were wounded or maimed. Yet these casualty figures convey very little of that war’s horrors, both for those who fought in the war and especially for the peoples of Indochina. In Vietnam itself, the economy and natural environment were devastated, and well over 3 million Vietnamese were killed, more than two-thirds of them civilians. Overall, at least 3.5 billion people are believed to have died as a direct or indirect result of the more than 14,500 wars that have been waged during the 5,000 years since the dawn of human civilization (Beer 1981).

The direct and indirect costs of warfare, and especially the tragic loss of human life, have elicited harsh criticism of war throughout the ages. The ancient Greek historian Plutarch (46-120) complained in the first century C.E. that “the poor go to war, to fight and die for the delights, riches, and superfluities of others” (Plutarch 1948, p. 167) According to Benjamin Franklin (1706–1790), one of America’s founding fathers, “there never was a good war or a bad peace” (quoted in Barash and Webel 2002, p. 12). Ernest Hemingway, a badly wounded World War I veteran and author of the famous antiwar novel *A Farewell to Arms*, agreed: “Never think that war, no matter how necessary, nor how justified, is not a crime” (Hemingway 2003, p. 233). And the famous British philosopher and pacifist Bertrand Russell warned at the beginning of the twentieth century that “either man will abolish war, or war will abolish man” (Russell 1915).

The march of technology has radically altered the scope and nature of war over the centuries. Technological progress has increased the need to mobilize the entire nation for military-industrial and other production in support of the war effort (the war’s “home front”), but has also made civilian populations a legitimate target for the military in what is often referred to as “total war,” a twentieth-century invention. The technological ability to use lethal weapons at a distance has escalated from primitive warfare’s bow and arrow to today’s supersonic jet and intercontinental ballistic missile, both of which can deliver deadly munitions at a speed of thousands of miles per hour and with pinpoint accuracy. This quantum leap has been matched by similar technological advances in destructive power, from the swords and spears of medieval combat to the massive explosive force of the thermonuclear bomb—measured in millions of tons (megatons) of TNT and capable of completely obliterating even the world’s largest cities.

In the age of nuclear and other weapons of mass destruction, some commentators suggest that their sheer destructiveness has made war obsolete, because no rational goal could be achieved by using such doomsday weapons that are endangering the very existence of mankind and indeed the survival of all life on the planet. For example, the total U.S. nuclear arsenal in 1990 was about 3,200 megatons of TNT, whereas the entire explosive power detonated by all militaries in World War II was approximately three megatons—including the two atomic bombs dropped on Hiroshima and Nagasaki in August 1945, which had the explosive force of 12 and 20 kilotons, respectively. Some scholars believe that the detonation of as little as 100 megatons of TNT, a tiny fraction of the world’s stockpiles of nuclear arms, could trigger a “nuclear winter”—the prolonged darkening and cooling of the planet (temperatures could plummet as much as 50 degrees Fahrenheit). After a nuclear exchange, the huge quantities of smoke and soot generated by the resulting firestorms would rise into the upper atmosphere and absorb incoming solar heat and light, thereby making the Earth cold, dark, and eventually uninhabitable (Sagan and Turco 1990). Even though wars are still taking place, causing immense destruction and misery, the threat of nuclear Armageddon has fostered powerful peace and antiwar movements that are not only deterring the nuclear-weapon powers from using or even testing their strategic arsenals, but also instilling the increasingly widespread belief that war is an illegitimate method for settling grievances.
WAR AND PEACE

War and Peace by Leo Tolstoy (1828–1910) is arguably the world’s greatest epic novel. Written and published in the monthly Russkij Vestnik from 1863 to 1869, the work depicts the years leading up to and including Russia’s wars with Napoleon from 1805 to 1812. The novel immortalizes the quiet heroism and spiritual strength of the Russian people in a time of national crisis and historical transition. War and Peace began as a social novel called The Decembrists about a Russian Decembrist returning from Siberian exile in the 1850s. As Tolstoy worked he realized that in order to describe his hero he would first need to understand his formative years during the Napoleonic wars. A lasting trace of this original conception is the character of Pierre Bezukhov, the hero of the original novel (named Pyotr Labazov) and a main protagonist in War and Peace. What began as a contemporary social study grew into a vast, vivid tableau of early-nineteenth-century Russian life that goes beyond historical fact to capture the emotional, psychological, and moral fabric of the time.

TOLSTOYAN WISDOM IN WAR AND PEACE

War and Peace reflects the deep imprint of French culture on nineteenth-century Russian life, not least in the aristocratic characters’ frequent use of French. And yet just as the vast Russian countryside in the novel engulfs the invading French army, so Tolstoy’s massive literary landscape assimilates French and other cultural influences into a synthetic creation that encompasses all of life.

In War and Peace characters are born, they marry, they decay, and they die. These events occur on a clock that ticks on with slow, implacable calm. This has led some readers to sense in the novel a spirit of fatalism. But War and Peace is also a freshly inspiring vision of the world’s physical plenitude and of the meaningful moral choices it offers. Many of the novel’s greatest scenes, such as Natasha Rostova’s first ball, the Rostov’s wolf hunt, and Prince Andrei’s vision of the “lofty infinite sky” as he lay wounded on the battlefield at Austerlitz, are among the most enthralling moments in world literature.

Almost all of the main protagonists in War and Peace find happiness in a balanced, mature view of the world as a place where joy and tragedy, moral choice and providential design, are present in equal measure. These characters discover that their individual lives are both finite and full of possibility, both solitary and also part of an organic tapestry of human evolution and history. Only Prince Andrei is unable to reconcile his noble ideals with reality. He is the novel’s one tragic hero.

If there is an overt ideological thesis in War and Peace, it is that great men do not move history but are its slaves and that free will is an illusion, albeit a necessary one to help us get through everyday life. Tolstoy takes particular aim at Napoleon, who arrogantly believes that he shapes events; at historians who accept the great man theory of historical evolution; and at all manner of strategists, military and otherwise, who believe that rational planning affects the outcome of events.

In Tolstoy’s novel those characters who live spontaneously are wise and productive because they are in sync with the forces of history and nature. Kutuzov defeats Napoleon not because of strategic planning (he sleeps before the Battle of Austerlitz while his military strategists quibble) but because he instinctively senses the inevitable course of events. Pierre grows wise and finds happiness...
after he gives up his Utopian schemes and accepts the world in its beautiful unpredictability.

THE NOVEL IN AN AGE OF SOCIAL UNREST
Tolstoy's initial work on The Decembrists and the early drafts of War and Peace occurred when he was growing concerned about the impending Great Reforms of Alexander II, begun in 1861. Tolstoy, an aristocrat, believed that the centuries-old system of aristocratic privilege and serfdom, while imperfect, was superior to the chaos—political, social, and spiritual—that the reforms would unleash. Tolstoy's social conservatism is evident in the work's idealized depiction of the landlord—peasant relationship at the beginning of the century. According to prominent Soviet scholar Viktor Shklovsky, Tolstoy distorts historical facts to further his ideological agenda. A prominent example of this described by Shklovsky is the author's suppression of the real reason that Princess Marya's peasants at Bogucharovo rebel in book three, part two, when she offers to take them with her to Bald Hills; because they believed that, by staying at Bogucharovo, they would be freed by Napoleon. Rather, Tolstoy's portrayal of the peasants gives the impression that their uprising was a senseless, isolated event, motivated by their eccentricity instead of their deep-seated dissatisfaction with the social status quo.

Although Shklovsky and some other scholars rightly discover strains of social conservatism in the novel, they reduce the great epic to a web of self-serving artistic illusions. A more likely source of Tolstoy's idealized portrayal of the peasant—landlord relationship is the author's lifelong attraction to the ideals of national unity, social harmony, and universal fellowship of human beings. We may read War and Peace as Tolstoy's heroic attempt to create for his discordant Russian society of the 1860s a mythical past in which Russians were secure in their collective identity and unified in their response to a national crisis.

FORM OF THE WORK
When it first appeared, War and Peace was a radical departure from the traditional form of the European novel. The work combines elements of the psychological novel, historical novel, family chronicle, epic, and Bildungsroman. It has astonished and confounded readers with its deluge of detail, its vast array of characters who seem to appear and disappear at random, and its inclusion of historically-philosophical essays throughout. Scholars differ about whether the work's idiosyncratic form was intended or “a splendid accident,” as American writer and critic Henry James called it. Twentieth-century scholars suggest that the novel's unconventional form intends to show that real life, like history, does not unfold in neat, narrative patterns. Other scholars argue that despite its strangeness the work contains concealed artistic patterns and unifying aesthetic principles.

Despite its sprawling canvas (approximately 365 chapters, or 1,500 pages in the original publication), War and Peace focuses the reader's deepest sympathies on Pierre Bezukhov and the novel's other four main aristocratic protagonists: Prince Andrei Bolkonsky, Nikolai Rostov, Natasha Rostova, and Princess Marya Bolkonskaya. Tolstoy presents their journeys with extraordinary lifelike realism, and he describes how their personal destinies become intertwined with the encroaching forces of war and history.

So interconnected do the “peace” and “war” sections of the novel become that it appears virtually impossible to disentangle them. Power politics, schemes, and stratagems are as present in the St. Petersburg drawing rooms as on the battlefield, and characters are as apt to achieve spiritual illumination in the throes of war as in the joys of family life. The “peace” of the novel’s title refers not only to peacetime but also to the spiritual tranquility characters seek amid the confusion of modern life.

FUTURE IMPACT
War and Peace has inspired generations of Russian writers and artists, who have tried to recreate Tolstoy’s expansive vision and have regarded Tolstoy’s masterpiece as a model for recording the unique destiny of the Russian people. Among the works that War and Peace has influenced are Mikhail Sholokhov’s novel The Quiet Don (1928–1940), Boris Pasternak’s Doctor Zhivago (1957), and Vasily Grossman’s Life and Fate (1959). Sergei Prokofiev’s operatic version of War and Peace, a masterpiece in its own right, beautifully transports to the stage the deep patriotic currents of Tolstoy’s novel, as well as the majestic calm of Tolstoy’s omniscient narrative voice. Tolstoy’s novel remains required reading in Russian schools, and ordinary Russians frequently can recite by heart passages from their adored classic. Even Joseph Stalin, infamous for his ability to harness the power of art for political purposes, recognized the potency of War and Peace when he ordered the book to be included in a propaganda series called “Books for Victory” during World War II (1939–1945).

WAR CRIMES
The notion of crimes of war has been known in the Western legal tradition since classical antiquity. For the ancient Greeks it was part of Hellenic customary law that provided some basic if ill-defined norms for the protection of civilians, suppliants, and prisoners in warfare between the Greek states. While this notion has persisted as the “laws and customs of war,” it was only with the incipient development of a body of international law at the end of the nineteenth and beginning of the twentieth centuries that it began to take shape in its modern form as a central category in the body of norms whose aim is to regulate the violence of armed conflict. The “laws and customs of war,” as the name indicates, apply only in the context of armed conflict. As the dual terminology “laws” and “customs” also implies, in the modern period these norms are regarded as having a dual basis. On the one hand, they are defined by the body of statutory law that has developed since the first Hague Conventions adopted around the beginning of the twentieth century. On the other hand, such conventions represent only one source of the international law of armed conflict. The codifications do not exhaust this body of law, which also arises from the customs and usages of warfare as reflected in the practices of nations.

Three major phases of development of the notion of war crimes in the modern period can be identified. The first begins with the adoption of the Hague Conventions of 1899 and 1907, regulating the conduct of hostilities and the employment of various kinds of weapons and modes of warfare. Most immediately relevant to war crimes is the 1907 Hague Convention IV on “The Laws and Customs of War on Land” and particularly its provisions defining the limits of military necessity and limiting the violence that may be employed against cities and other civilian targets (Articles 22–28). While the treatment of prisoners of war is addressed in the Hague Conventions, it was the Geneva Convention of 1929 that provided the basic legal framework for this subject in the pre–World War II (1939–1945) era. While the distinction between “Geneva law” and “Hague law” was widely regarded as fundamental in earlier periods, it has, as we will see, largely ceased to have any relevance in the contemporary period.

The experience of “total war” in the European and Asia-Pacific theaters in World War II involved the total destruction of major civilian centers, the displacement of entire populations, industrialized murder, civilian deaths in the tens of millions, and devastation on a scale hitherto unimagined. Total war led to a widespread recognition that the laws of war had to be revised so as to reflect the exigencies of a new age. The first major step in this direction was taken by the victorious Allies in the creation of two international criminal tribunals in Nuremberg and Tokyo to try German and Japanese military and civilian leaders for crimes against peace, war crimes, and crimes against humanity. The definition of “war crimes” in the Nuremberg Charter provided an important and expansive definition of the scope of such criminal conduct:

Violations of the laws or customs of war. Such violations shall include, but not be limited to, murder, ill-treatment or deportation to slave labor or for any other purpose of civilian population of or in occupied territory, murder or ill-treatment of prisoners of war or persons on the seas, killing of hostages, plunder of public or private property, wanton destruction of cities, towns or villages, or devastation not justified by military necessity.

For the first time governmental and military leaders were held criminally responsible as individuals and punished by the Nuremberg and Tokyo tribunals for their roles in planning, instigating, ordering, or perpetrating such war crimes. In addition, building upon the Nuremberg and Tokyo Charters, the Allies created a legal framework for national war crimes tribunals that convicted thousands of Japanese and German war criminals of war crimes. This step marks the decisive move into the contemporary age of individual accountability for war crimes and other violations of international law regulating armed conflict.

During the same period in the aftermath of World War II, the four Geneva Conventions of 1949 and the Genocide Convention of 1948 also represent major landmarks in the development of the contemporary legal framework regulating armed conflict. The Geneva Conventions of 1949 greatly expanded and refined this framework and also made decisive contributions to the law of war crimes. Particularly
grave violations falling within the category of war crimes were designated as “grave breaches” of the conventions. These include: wilful killing; torture or inhuman treatment; biological experiments; unlawful deportation or transfer, taking of hostages, etc. (The 1977 Protocol 1 to the 1949 conventions greatly expands the category of grave breaches, particularly by including various limitations on the conditions under which civilian targets may be made the object of attack.) Further, for the first time the coverage of this body of law was extended to noninternational conflicts. That is, previously war crimes by definition involved violations committed in time of war or serious armed conflicts between nations. The hitherto seemingly inviolable principle of national sovereignty had protected governments from interference with what they did within their own territory to their own citizens. The development of the category of “crimes against humanity” represented one important prong in limiting this principle, and Article 3 of the 1949 Geneva Conventions represented another. The coverage of the 1949 conventions as to war crimes was extended further by the two 1977 protocols to the 1949 conventions, the first covering international conflicts the second internal ones. Common Article 3, so called because it is found in all four of the 1949 conventions, extends basic minimum protections of international law to purely internal conflicts and thus brings the notion of war crimes into the sphere of the kinds of internal conflicts that have been so prevalent in the post–World War II era. Common Article 3 provides:

In the case of armed conflict not of an international character occurring in the territory of one of the High Contracting Parties, each party to the conflict shall be bound to apply, as a minimum, the following provisions:

1. Persons taking no active part in the hostilities, including members of armed forces who have laid down their arms and those placed hors de combat by sickness, wounds, detention, or any other cause, shall in all circumstances be treated humanely, without any adverse distinction founded on race, colour, religion or faith, sex, birth or wealth, or any other similar criteria.

To this end the following acts are and shall remain prohibited at any time and in any place whatsoever with respect to the above-mentioned persons:

(a) Violence to life and person, in particular murder of all kinds, mutilation, cruel treatment and torture;
(b) Taking of hostages;
(c) Outrages upon personal dignity, in particular, humiliating and degrading treatment;
(d) The passing of sentences and the carrying out of executions without previous judgment pronounced by a regularly constituted court affording all the judicial guarantees which are recognized as indispensable by civilized peoples.

The third phase in the development of the body of law defining and punishing war crimes began with the creation of the Ad Hoc International Criminal Tribunals for Rwanda and the former Yugoslavia (ICTR and ICTY) in 1993–1994. Whereas war crimes had not been punished by international tribunals since Nuremberg and Tokyo, the ICTY and ICTR ushered in an age of the institutionalization of such prosecutions, reaching fulfillment in the creation of the permanent International Criminal Court (ICC) in the Hague in 2002. All three of these bodies have made important contributions to the definition, jurisprudence, and punishment of war crimes, as have the so-called international “hybrid tribunals” in East Timor, Kosovo, Bosnia, Sierra Leone, and Cambodia.

The statutes of all three of these international criminal tribunals include war crimes as one of the major categories of violations of international law within the jurisdiction of these courts. (See, e.g., ICTY Statute Articles 2 and 3; ICC Statute Article 8.) The Appeals Chamber of the ICTY has clarified the relations between the categories of “grave breaches,” other violations of the “laws and customs of war” defined by the Hague and Geneva Conventions, and common Article 3. It has ruled that all of these norms are war crimes and that the previous distinction between “Hague law” and “Geneva law” is no longer relevant. (See, e.g., the Tadić Jurisdiction Decision, para. 87, and the Celebici Appeals Judgment, paras. 132–133.)

The statute of the ICC makes this clear in Article 8 by specifying that the category of war crimes includes grave breaches and “other serious violations of the laws and customs of war applicable in international armed conflict” as well as common Article 3 and other “serious violations of international law applicable in non-international armed conflict.” The category of war crimes has thus expanded to encompass a very wide range of offenses committed in international or internal conflicts. These offenses have also become much more clearly defined than in previous eras. In particular, the jurisprudence of these courts has provided authoritative discussions and definitions of the elements of these offenses. This represents an important contribution to the interpretation and applications of such crimes because the post–World War II trials had left them largely undefined. Most recently, the ICC has promulgated the Elements of Crimes, which also includes definitions of each of the key components of all major crimes of war. As the ICC assumes an ever more prominent role in the application of international humanitarian law, its definitions of
the elements of war crimes is likely to prove to be of decisive influence.

**WAR OF 1898**

The Spanish-American War of 1898 presented a series of opportunities and consequences for both nations. For example, Spanish historiographers have evaluated the war as a disaster after which Spain experienced decades of disarray and disorder. For Cuba, the Philippines, Hawaii, and Puerto Rico the year 1898 represented a transition from colony to nation status, although not without fierce opposition from resistance fighters such as Emilio Aguinaldo and leaders such as Queen Liliuokalani of Hawaii who fervently protested foreign encroachment on their sovereignty. Moreover, U.S. historians have debated whether to describe the war as an “accidental” conflict, a war for territorial expansion, or an inevitable war induced by public opinion. In the end, as “benevolent” victors, most Americans believed that they had acted as humanitarian benefactors on behalf of their neighbor Cuba.

A major cause of disarray on the island had been the appointment by Spain of Valeriano Weyler y Nicolau as the governor of Cuba in 1896, a period of heightened insurgency. His cruelty captured the attention of American newspapers dominated by William Randolph Hearst’s sensationalist *New York Journal* (the Yellow Press). Governor Weyler disturbed humanitarian observers by establishing “reconcentration” camps that were designed to confine the peasants in detention facilities and thus isolate the insurgents, who theoretically would remain outside the quarantined areas. Although unintended, conditions in the camps caused the malnutrition of hundreds of thousands. The estimates of those who died from disease and hunger approach 321,934.

In 1898 a private letter written by the Spanish foreign minister, Enrique Dupuy de Lome, who was stationed in Washington, characterized U.S. President William McKinley as “a would be politician.” Cuban revolutionaries intercepted the communiqué and offered it to the American print media. Portions of the infamous “de Lome letter” were published throughout the United States.

The primary event that justified going to war occurred in the middle of the controversy about Governor Weyler and the danger to American investments on the island. Americans labeled it “fiendish treachery” on February 15, 1898, when the American battleship **USS Maine** suddenly and without warning exploded in Havana Harbor. Out of a complement of 354 officers, 266 perished in the explosion. The **Maine** had been situated in what had been recognized as Spanish waters. The cause of the destruction of the **Maine** was uncertain. Nonetheless, on March 28 a report of the U.S. Naval Court of Inquiry determined that the explosion had been caused by a mine planted by Spanish operatives. On April 19, after a short period of deliberation, Congress voted for the immediate outbreak of hostilities against the Spanish forces in Cuba by a margin of 311 to 6 in the House and 42 to 35 in the Senate.

The first battle of the war occurred halfway across the world from Cuba, on the high seas in Manila Bay in the Philippines. The famous orders at Manila Bay to “fire when ready” were issued by the commander of the Asiatic Squadron, Commodore George Dewey. Dewey transferred the fleet from Hong Kong to the Philippines when briefings arrived on April 24. Dewey’s strategy included the broadsiding of the Spanish fleet, which had been caught by surprise and ultimately proved obsolete compared with the U.S. fleet. In Cuba the American forces first landed at Guantánamo Bay and then at San Juan Hill (the site of Teddy Roosevelt’s dangerous assault with the American volunteer force known as the Rough Riders), El Caney, and Santiago de Cuba. The Spanish surrendered at Santiago de Cuba on August 12. Overall, the United States lost 379 troops in combat and an estimated 5,000 as a result of disease and tropical conditions.

The war concluded with the Treaty of Paris, which was signed on December 10, 1898. The Cuban government was denied the opportunity or right to participate in the peace negotiations. Congress followed the cessation of hostilities with the Platt Amendment, guaranteeing the right of the United States to intervene militarily in Cuba any time internal disarray attracted its attention.

In the aftermath of the war the United States acquired Hawaii, Guam, the Philippines, Cuba, Puerto Rico, and the Wake Islands. Those territorial acquisitions allowed the United States to penetrate foreign markets, most importantly China, and end a decade of economic depression. The United States elected to maintain a naval station at Guantánamo Bay that proved to be a vital security installation. Securing Cuba had been a longtime priority because of its proximity to American shores and former control by a European government. President McKinley delivered the Imperial Gospel speech in 1899, in which he offered a justification for conquering foreign territories that seemed reasonable to business advocates,
the military, and imperialist patriots: “to uplift, civilize and Christianize them.” Seemingly overnight America became a world colonial power.

WAR ON POVERTY
The war on poverty of the John F. Kennedy (1917–1963) and Lyndon B. Johnson (1908–1973) administrations grew out of the civil rights movement of the 1950s and continued from 1964 to 1981. It had antecedents, beginning with the 1941 state of the union address of President Franklin Delano Roosevelt (1882–1945), in which he enunciated “freedom from want” as one of four fundamental human rights. This pronouncement was taken as a program by Governor W. Averill Harriman (1891–1986) in New York state from 1954 to 1958.

A more direct antecedent had developed in New York City in 1946 at the LaFargue Psychiatric Clinic at the Saint Philip’s Episcopal Church in Harlem, where Shelton Hale Bishop (1889–1962) served as rector. The clinic was named for Paul LaFargue (1842–1911), a medical doctor and the son-in-law of Karl Marx (1818–1883). Its director was psychiatrist Frederic Wertham (1895–1981). Thurgood Marshall (1908–1993) and Kenneth B. Clark (1914–2005) were members of this church. Wertham, Marshall, and Clark collaborated to help the NAACP win the 1954 U.S. Supreme Court case, Brown v. Board of Education of Topeka, which outlawed segregation in public schools.

MOBILIZATION FOR YOUTH
Three years later, an organization called Mobilization for Youth was incorporated on the Lower East Side of New York City by the Henry Street Settlement House with the collaboration of the Columbia University School of Social Work. In 1959 the National Institute of Mental Health (NIMH), which had just received increased allocations from Congress, provided a two-year planning grant, and Columbia sociologists Richard A. Cloward (1926–2001) and Lloyd Ohlin were retained as consultants. Cloward and Ohlin had developed an extension of Durkheim-Merton alienation/anomie opportunity theory in sociology, and in 1960 they published Delinquency and Opportunity, in which they argued that delinquents behaved in unapproved ways precisely because they had accepted approved social goals but found no socially approved means by which they could attain those goals, and so resorted to unapproved means. To motivate delinquents to adopt not only the goals but the approved means, opportunity must be provided. In support of this idea, Leonard S. Cottrell Jr. (1899–1985) of the Russell Sage Foundation testified on March 10, 1960, before a subcommittee of the House Appropriations Committee that delinquency was not so much a matter of curing sick individuals but of curing sick communities.

Mobilization for Youth’s final planning report, “A Proposal for the Prevention and Control of Delinquency by Expanding Opportunity,” was presented December 9, 1961, and was submitted to the NIMH for funding. The NIMH, the President’s Committee on Juvenile Delinquency and Youth Crime (PCJDYC), the U.S. Department of Labor and other federal agencies, the New York City government, and the Ford Foundation subsequently funded Mobilization for Youth for $12.5 million for three more years. In April 1962 Mobilization for Youth submitted “Youth in the Ghetto: A Study of the Consequences of Powerlessness and a Blueprint for Change” to the PCJDYC review committee, headed by Cottrell. This committee recommended that one million dollars be granted to the program. The city of New York, under Mayor Robert Wagner (1910–1991), then allocated $3.5 million from its antipoverty funds. The Department of Labor under the Manpower Development and Training Act granted another half million dollars for job training aspects of the program. The initial directors were Cloward and George A. Brager (d. 2003).

In his first race for the office of New York City mayor in 1977, Edward Koch coined the terms poverty pimp and povertician to refer to Raymon Velez of the South Bronx. Velez, born in Puerto Rico in 1930, had developed beginning in 1968 a network of organizations in the South Bronx funded by the Office of Economic Opportunity (OEO). He had earned a BA in history and political science from Inter-American University of Puerto Rico, after which he became a school teacher. Immigrating to New York, Velez became a social worker. On the basis of his antipoverty network, which provided needed social services and jobs to residents of Puerto Rican neighborhoods,
he gained popularity and turned this social and economic success toward politics. Velez became the “boss” of South Bronx politics, securing the election of many Puerto Ricans to city, state, and federal office. In the 1980s he was elected to the New York City Council, a step downward in his estimation, and served only briefly. This evidently was a slap at Democratic primary opponent, Herman Badillo, whom Velez supported. The rise of Puerto Rican political power in the South Bronx was attained at the expense of Jewish politicians who previously had controlled the area. Changing demographics accounted for the transition.

THE FEDERAL ANTI-POVERTY PROGRAM OF THE KENNEDY-JOHNSON ADMINISTRATIONS

In the presidential election campaign of 1960, John F. Kennedy promised a “war against poverty and degradation” and “an economic drive on poverty” to address the high and persistent unemployment of the 1957–1958 and 1959–1960 recessions. His thought on this issue was based largely on John Kenneth Galbraith’s (1908–2006) *The Affluent Society* (1958), especially chapter 23, “The New Position on Poverty.” Upon Kennedy’s election, the president’s Council of Economic Advisors and the Budget Bureau immediately advocated a tax cut, accompanied by an increase in spending as a Keynesian economic remedy for the recession. The result would be a deliberate increase in the federal deficit. This was an attempt to establish Keynesian economic theory as a viable basis for government economic policy. The president accepted this advice.

The particular cabinet departments and programs involved in the spending increases and tax cuts were determined in other ways. In March 1961 Kennedy called a President’s Conference on Juvenile Delinquency, chaired by his brother Robert F. Kennedy (1925–1968), the new attorney general. Based upon the recommendations of the March conference, the PCJDYC was established on May 11, 1961. The PCJDYC was to finance projects seeking a solution to juvenile delinquency. Robert Kennedy selected his friend David Hackett as executive director.

In September 1961 Congress passed the Juvenile Delinquency and Youth Offenses Act, which authorized demonstration and training programs in finding “the most effective ways of using total resources to combat juvenile delinquency in local communities.” It authorized an expenditure of $10 million over three years for the program. In 1962 the committee gave planning grants to agencies in sixteen cities. The act also funded Mobilization for Youth in late 1961 to develop a plan of action to curb juvenile delinquency on New York’s Lower East Side. Cloward then lent his principal assistant, sociologist James A. Jones (1932–1992), to Kenneth Clark to design a similar program for Harlem. Clark and Jones in 1962 established Harlem Youth Unlimited Inc. (HARYOU), of which Jones became research director. Harlem Congressman Reverend Adam Clayton Powell Jr. (1908–1972), the new chairman of the House Education and Labor Committee, formed a rival Harlem organization, Associated Community Teams (ACT). He then insisted that HARYOU be merged with ACT, and when this was accomplished, Clark resigned. He was replaced by ACT executive director Livingston Wingate (1916–1995), Powell’s assistant.

In December 1962 President Kennedy asked his Council of Economic Advisors chairman, Walter W. Heller (1915–1987), to pull together all available information on the poverty issue. Heller assigned this task to council member Robert J. Lampman (1920–1997). He and Heller suggested that Kennedy read socialist Michael Harrington’s (1928–1989) *The Other America: Poverty in the United States* (1962), along with Leon Keyserling’s (1908–1987) *Poverty and Depression in the United States* (1962). Harrington was considered a “responsible radical,” because he was a follower of former Trotskyist Max Schachtman, whose tactic was to “bore from within.” This meant that instead of running Socialist Party candidates for elective office, the party would support Democratic Party candidates. Harrington, thus, had been a well-known worker for left and liberal organizations and journals throughout the 1950s. In July 1959, he wrote an article on poverty for *Commentary Magazine*, and it was from this article that the book *The Other America* grew. In an approving commentary of Galbraith’s book *The Affluent Society* (1958), he noted the existence of 50 million impoverished people in the United States, about one quarter of the total population. Poverty persisted from generation to generation, helped by what Oscar Lewis called a “culture of poverty,” a non-Marxist idea. It was precisely this idea that recommended him to the Kennedy administration, because it undercut left leadership of the anti-poverty struggle. Harrington’s entire body of work thus led to an eager anticipation of the book, and accounted for the wide extent of its positive reception. That he had worked for Catholic organizations did not hurt his acceptance by the president, even though he had lapsed from the faith by then. After Lampman reported that the U.S. poverty rate was increasing, Kennedy directed Heller to include a “war on poverty” in the 1964 White House legislative package for Congress.

On the day after Kennedy’s November 22, 1963, assassination in Dallas, Heller met with President Johnson and suggested to him that a war against poverty might be a good way to begin his presidency. Johnson agreed. In his 1964 state of the union address, titled “The War on Poverty,” he called on Congress to enact a package of measures embodying programs that would eliminate...

**THE EQUAL OPPORTUNITY ACT**

David Hackett and Richard Boone of PCJDDC suggested that their community action model should be the vehicle for this war on poverty. Other departments proposed programs over which they had jurisdiction. At this point, the Budget Bureau, headed by economists Kermit Gordon (1916–1976) and Charles L. Shultze, became involved. Budget Bureau staff member William B. Cannon wrote a memorandum suggesting that the community action program begin with ten demonstration areas across the country, and that a development corporation be established in each. Shultze suggested similarly that poverty funds be allocated to “pockets of poverty,” rather than uniformly across the country. He also suggested using the term *action program*, from Cannon’s memo, rather than *development corporation*. Someone added *community* to *action program*, and the community action title of the proposed legislation was born. The task force developed the plans for an organization to conduct the “war on poverty,” and submitted them to the president on March 15, 1964; he then disbanded the group. The next day, on the basis of the task force report, Johnson delivered a message to Congress calling upon it to enact legislation creating such an agency. He stated that the program would not consist of top-down planning from Washington, but would involve the talents of people from all over the country, at every level of society. He also called for the establishment of an office of equal opportunity. In testimony before Congress in 1964, Shriver listed 137 people who had participated in writing the legislation. On August 29, 1964, Congress passed, and Johnson signed into law, the Equal Opportunity Act of 1964. The act created the OEO, and on August 30, 1964, Congress gave the OEO $947.7 million for ten programs.

The OEO was initially lodged in the Office of the President, but subsequently became an independent agency. Shriver was named director of the OEO and served until 1968. Economist and AFL-CIO lobbyist Hyman H. Bookbinder, a member of Shriver’s 1964 task force, became associate director.

The Equal Opportunity Act also created an OEO Advisory Committee of fourteen, which was appointed by President Johnson on January 29, 1965. Perhaps the most important arm of the OEO administrative structure, although it had no program responsibilities, was the Office of Research, Plans, Programs, and Evaluation, which might be called the “war room” of the war on poverty. Here were placed those economists who had actual experience in administering economic planning.

The first director of this office was Joseph A. Kershaw (1913–1978), who served from 1964 to 1966. He was succeeded by Robert A. Levine (1966), Robinson G. Hollister (1966–1968), and Walter Williams (1968–1969). Levine attempted to establish a five-year plan to end poverty that proposed a national negative income tax program to replace Aid to Families with Dependent Children (AFDC). The OEO funded the New Jersey Negative Income Tax demonstration project to estimate the cost of the program.

The war on poverty required for its success a definition of poverty and a means of measuring it. In March 1965, Kershaw and the Office of Research, Plans, Programs, and Evaluation used the work of economist Mollie Orshansky of the Social Security Administration to establish such a definition. Two months later, the OEO officially adopted the Orshansky poverty thresholds as a working definition of poverty.

The unique feature of the Equal Opportunity Act was Title II: the Rural and Urban Community Action Program. The OEO divided the country into seven to ten regions, each with a regional director. Fieldworkers in the Washington headquarters traveled to regions to help establish and monitor the operation of community action agencies located in the major cities of each region. In addition, the OEO funded national organizations to facilitate theoretical and empirical research on the issue of poverty. Chief among these were the Harvard-MIT Joint Center for Urban Studies, the National Association for Community Economic Development, the Institute for Research on Poverty, the Urban Institute, the Center for Community Economic Development, and the National Rural Center.

**THE INSTITUTE FOR RESEARCH ON POVERTY**

The Institute for Research on Poverty was established at the University of Wisconsin by Lampman, who was considered the leading expert on the economics of poverty. Its first director was Harold W. Watts (1966–1971). By 1985, with the OEO no longer in existence, oversight of the Institute for Research on Poverty had shifted to the assistant secretary of Health and Human Services for Planning and Evaluation. By 1996 the institute was no longer the national poverty center, but only one among several area poverty centers. The Center for Community Economic Development in Cambridge, Massachusetts, was codirected in 1971 by Geoffrey P. Faux, who had been director of the OEO Economic Development Division from 1967 to 1970. The National Rural Center was established in 1975, with F. Ray Marshall as president and director. When President Jimmy Carter named Marshall his secretary of labor in 1977, John M. Cornman replaced him.
Half of the OEO's community action program funds went to prepackaged national programs such as Head Start. The other half went to local initiative programs developed by the community action agencies themselves.

New York City, where the theory and operational model for the war on poverty had been developed, received feedback from the federal government. In 1962 Mayor Wagner had created a Council on Poverty and an Anti-poverty Operations Board. Surgeon Arthur C. Logan (1909–1973) was the first chairman of the community action program under Wagner. Wagner was defeated in 1965 by former congressman John V. Lindsay (1921–2000), who in 1966 established a Mayor's Task Force on Poverty, headed by Mitchell Sviridoff (1918–2000). The task force recommended the establishment of a superagency comprised of all agencies having any responsibility for providing services to the poor. On September 15, 1966, Lindsay established the Human Resources Administration, which included the Community Development Agency and the Manpower and Career Development Agency, among other agencies. The Community Development Agency was designated the New York City community action agency under the OEO. Sviridoff served as head of the Human Resources Administration from 1966 to 1967.

New York's Community Development Agency was headed by George Nicolau from 1966 to 1967. He was replaced by Major Owens in 1968, and Owens served until 1973. In 1968 the agency wrote a grant proposal to NIMH for a Brownsville Community Council economic advocacy planning project. The NIMH funded the proposal, its first grant to a community action agency to conduct economic advocacy planning, and the Brownsville Advocacy Planning Agency was born. The agency's staff included graduate students in economics from Yale and Columbia universities.

A participant in the 1949 founding of the NIMH, and a member of its advisory board at the time of this grant, was Eli Ginzberg (1911–2002), director of the Conservation of Human Resources Project of Columbia Business School. His staff at Columbia in 1956 consisted of two economists and four psychologists and social psychologists. The grant to the Brownsville Community Council was a departure, as advocacy planning was developed largely by architects and city planners. Columbia's School of Architecture, for example, was responsible for the creation of the Architect's Renovation Committee of Harlem and the East Harlem Studio of the Real Great Society Uptown. In the 1950s the NIMH had established a unit to finance outside research. In response to Johnson's war on poverty, the NIMH established centers for minority group and urban mental health problems. It was the conjunction of these institutions and forces that enabled the grant to the Brownsville Community Council in 1968.

Robert Kennedy resigned as attorney general and was elected senator from New York in 1964. In 1966 he and Jacob Javits (1904–1986), the senior senator from New York, introduced the Kennedy-Javits Amendment to the Equal Opportunity Act, creating a new Title I-D, the special impact program (SIP). This title caused a shift in the OEO toward community-controlled business development through community development corporations. The community development corporations were designed as community holding companies or community trusts. To administer the new program, the OEO established the Economic Development Division, under which the Bedford-Stuyvesant Restoration Corporation in Brooklyn, New York, and the Hough Area Development Corporation in Cleveland, Ohio, were funded in 1966 as the first two community development corporations in the nation.

In 1967 the Edith Green Amendment placed a ceiling of 33 percent for representatives of the poor on a city's community action agency. In the meantime, Kenneth Clark in 1967 founded the Metropolitan Applied Research Center and served as president until 1975. The Metropolitan Applied Research Center received a grant of $190,000 from the Field Foundation. In 1970 the center and Howard University, with an $860,000 Ford Foundation grant, established the Joint Center for Political Studies in Washington, D.C., with Howard law professor Frank D. Reeves (1916–1973) as director.

From 1968 to 1969, New York's community action program guidelines made advocacy planning the highest project-funding priority, leading to the funding of the Pratt Institute's Center for Community Development; Harlem Commonwealth Council's (HCC) Commonwealth Holding Company, Inc., a subsidiary, with the Black Economic Research Center in Harlem as a major consultant; and the Brownsville Advocacy Planning Agency. These organizations were intended to provide economic expertise and advocacy for their respective communities in dealing with the City Planning Commission and other relevant city, state, and federal agencies in developing and locating commercial, industrial, and service enterprises.

The Ford Foundation, a major partner of the federal and city governments in the war on poverty, provided grants for advocacy planning to the Black Economic Research Center from 1968 through 1980. The center developed the theory that the major economic problem of black Americans was not labor market inequality but capital market inequality, which included access to the major stock and commodity exchanges, as well as to the Treasury Department, which represented capital interests, on a communal basis. Current capital reallocation was necessary, and the first stage of such a transfer was social capi-
tal, including infrastructure, and educational facilities with financing for operations.

Current income redistribution was also deemed necessary, along with future nondiscrimination in markets to maintain the gains achieved. These developments were a direct confrontation of the theory upon which the war on poverty was based—that a change of unmeasurable internal states of being could result in a measurable diminution of poverty in a finite and short period. It also confronted the theories of economists Gary S. Becker, Theodore Schultz (1902–1998), and Milton Friedman (1912–2006), which defined lifetime earnings as capital stock, human capital, and focused on future income distribution and not current income redistribution. This polemic was one of the sources for the development of the reparations argument in the black community. Reparations as a large lump sum would enable the purchase of capital assets by the residents of black communities, and avoid the necessity for politically impossible capital expropriation. This concept, which had been a tenet of black nationalist doctrine since the 1920s, began to gain academic and social respectability at the Black Economic Development Conference in Detroit in 1969.

DEVELOPMENTS UNDER NIXON
AND LATER ADMINISTRATIONS
The election of Richard M. Nixon (1913–1994) as president in 1968 heralded the demise of the OEO and the war on poverty. In April 1969, Donald H. Rumsfeld was appointed OEO director with the charge to dismantle the agency. He selected Richard B. Cheney as his assistant. Howard Phillips was appointed as OEO director in 1973 to succeed Rumsfeld. However, court decisions forced the administration to expend the funds appropriated, because the Equal Opportunity Act had a ten-year life by law. In 1970 amendments to the Equal Opportunity Act created SIP Title VII. Title VII funds went to, among other entities, the Federation of Southern Cooperatives, which created surplus-earning entities in rural areas of southern states. OEO programs were transferred to the Department of Health, Education, and Welfare, and to the Department of Labor. By the time Nixon resigned on August 8, 1974, the war on poverty was essentially over.

The coup de grâce occurred from 1974 to 1976 during the Gerald R. Ford (1913–2006) administration. Funding for OEO programs could now be legally cut, and the OEO was actually abolished by the Headstart, Economic Opportunity, and Community Partnership Act of January 4, 1975, which created the Community Services Administration (CSA), the name suggesting a retreat from community action by citizens to government provision of services to citizens in communities. For the horizontal relationships among equal citizens uniting to achieve a commonly determined purpose at the neighborhood level was substituted the old vertically hierarchical relationship between the rulers and the ruled.

From 1977 to 1981 the Carter administration attempted to resurrect the war on poverty by increasing funding for the CSA and enacting legislation expanding the SIP emphasis. Chief among the new institutions established by Congress was the National Consumer Cooperative Bank, signed into law in 1978 and opened for business in 1980, and the Rural Development Loan Fund, established in 1981. Both had boards of directors consisting of representatives elected by residents of low-income communities. The National Consumer Cooperative Bank made federally subsidized below-market-rate loans to consumer and producer cooperatives in largely urban areas. From the Community Economic Development Act of 1981, the Rural Development Loan Fund was to consist of all remaining funds from Part A of Title III of the Equal Opportunity Act and the funds from Title VII community development credit unions. It was located in the CSA, and provided one-percent interest rate loans for rural business purposes.

The OEO, the Rockefeller Brothers Fund, and the Ford Foundation had earlier financed the development of the idea for these financial institutions. Edward K. Hamilton and Belden Hull were hired as consultants by the National Rural Center and the Opportunity Funding Corporation (established in 1970) to design the bank as an experiment in development finance. The Opportunity Funding Corporation was an OEO demonstration project in community capital development, led by John Gloster, a former Atlanta insurance executive. The National Rural Center invited experts from Europe, Canada, and the United States to a conference at the University of Wisconsin to provide ideas on a design. The final design drew upon the Treasury Department’s new Federal Financing Bank, established in 1973. This design was negotiated largely at the Treasury Department with an interagency task force appointed by President Carter.

With Carter’s defeat by Ronald Reagan (1911–2004) after one term, however, the fate of the war on poverty was sealed. The Equal Opportunity Act was repealed on October 1, 1981. The Community Development Block Grant was established in 1981, ensuring that federal funds would not go directly to neighborhoods but would be filtered through established political groups at the state and municipal levels. Then CSA was abolished, although the Rural Development Loan Fund was allowed to remain.

Despite these developments, the national advocacy groups for community development corporations continued the battle against poverty, financed as before the war on poverty by religious organizations, universities, private foundations, and unsystematically by federal, state, and
local government. The war on poverty had degenerated from a massed frontal assault into a guerrilla war. In addition, the surpluses generated from the operation of community development corporations and cooperatives were plowed back into operations to help finance operations and expand capital equipment. And the national financial institutions still existed. As of 2005, at least 80 percent of counties in the United States still had community action agencies or community development corporations.

CONCLUSION
The war on poverty involved socially well-placed individuals using social science ideas to create new institutions in low-income communities, and at the national level to assist these local institutions. These individuals and institutions then engaged in actions that created historic events. The social science ideas reflected Keynesian economic theory, as well as opportunity theory in sociology and social psychology, and the political science theory of urban politics that maintained that urban neighborhood communities should be self-governing, independent political entities.

The new institutions created were, at the first level, community social service agencies in poor communities. The organizations responsible for these creations were private religious organizations, universities, and foundations. Using these community organizations as models, the federal, state, and local governments transformed their structures to replicate those of the private social service agencies for these functions, and wrote these changes into law. These practices thereby became obligatory for the nation as a whole and, importantly, became familiar to the electorate who were neither poor nor involved in service to the poor.

BIBLIOGRAPHY
Nuclear warfare consists of armed conflict between states in which one or more sides employ nuclear weapons. Because no war since World War II has involved nuclear weapons, how such a conflict would be triggered and executed is largely a matter of theoretical speculation. Furthermore, the sophistication and destructive scale of the nuclear weapons used against Japan pale in comparison to modern weapons. A nuclear war between two nuclear states would result in the deaths of hundreds of thousands, if not millions, of people. The areas surrounding locations hit with nuclear weapons would be highly contaminated with radioactive fallout. In addition, depending on the number of weapons used, such a war could have long-term devastating effects on the earth’s ecosystems and atmosphere. Because today only a few countries possess nuclear weapons, the number of conflicts that could conceivably escalate to nuclear war is limited. These countries include the United States, Russia, China, Great Britain, France, Israel, Pakistan, India, and most likely North Korea. Proliferation to additional countries remains a continual problem for international security.

The destructive power of nuclear weapons makes nuclear warfare fundamentally different from traditional conventional warfare. The single fifteen-kiloton bomb dropped on Hiroshima, for example, destroyed 80 percent of the city, immediately killing between 66,000 and 80,000 people and injuring roughly 70,000. As Wilfred Burchett (1945), the first journalist to report on the devastation, put it: “Hiroshima does not look like a bombed city. It looks as if a monster steamroller has passed over it and squashed it out of existence.” The city of Hiroshima estimates that the total killed from the explosion and subsequent radiation poisoning is over 240,000. Nagasaki saw high casualties as well, with 39,000 immediately killed and 25,000 injured, and many others who later died due to radiation poisoning.

How nuclear weapons would be used in war, and whether a nuclear war between two nuclear powers could even be won, has been a central problem facing military strategists and planners. Because of the devastating effects of nuclear weapons, they are less useful in battle than conventional weapons. However, because such weapons exist and because no country can be sure of what another’s
intentions would be in the event that they were to gain a
dominant nuclear advantage, the major nuclear powers
have continued to develop nuclear war strategies. That
said, nuclear powers have shown extreme caution when
conflict develops with other nuclear powers, out of fear
that a minor crisis could escalate into an unwanted
nuclear war; this was displayed during the 1962 Cuban
missile crisis. Nuclear powers have also been reluctant to
use their nuclear capabilities in conflicts against a non-
nuclear power, as with the United States in Vietnam or
Israel in its 1973 war with Egypt and Syria.

COUNTERFORCE, COUNTERVERSE,
AND MUTUAL ASSURED
DESTRUCTION

Nuclear strategy makes distinctions between counterforce
and countervalue. Counterforce strategies are intended to
affect an opponent’s capabilities, whereas countervalue
capabilities affect an opponent’s will. Counterforce targets
an opponent’s armed forces and military-industrial instal-
lations, limiting the opponent’s ability to retaliate in a
counterattack. A country that struck first in a nuclear war
would most likely employ a counterforce targeting strategy.
Countervalue strategies target an opponent’s cities—that
is, things of human and emotional value. A country that
feared a nuclear attack by an opponent would threaten a
countervalue retaliation with the hope that even the possi-
bility of its opponent losing one city would be enough to
deter a nuclear first strike. Of course, for a countervalue
deterrent to be effective, the country being deterred must
believe that at least some of its opponent’s nuclear arsenal
would survive a first strike. It also must believe that the
damage that that remaining arsenal could deliver would
outweigh the benefits gained from striking first. With
nuclear weapons it is oftentimes difficult to distinguish
between what constitutes a counterforce and what consti-
tutes a countervalue target. Military targets are often found
in population centers and given the large radius of damage
cauased by a nuclear attack it is extremely difficult to target
the one without hitting the other. For example, when U.S.
war planners began looking for military-industrial targets
across the Soviet Union after 1945, every sizeable Soviet
city was deemed to contain military targets.

The logic behind counterforce and countervalue, as
well as first-strike versus second-strike capabilities, is
encompassed in the idea of mutual assured destruction
(MAD). MAD describes a state of affairs in which both
sides’ nuclear forces are such that a sufficient percent
would remain after an attack that it would still be possible
to bring about the near total destruction of the attacking
state. The hope of MAD was that this mutual suicide pact
would prevent either side from ever being tempted to use
nuclear weapons. In order for MAD to be viable, however,
it required the United States and the Soviet Union to
stockpile large quantities of nuclear weapons and to
develop targeting lists of single targets that would be hit
multiple times. In addition, U.S. and Soviet force struc-
tures were designed to survive a possible first strike.
Achieving this involved spending on difficult-to-target
nuclear forces, such as submarines, hardened missile silos,
and continually in-flight bomber fleets.

MAINTAINING A STRATEGIC
BALANCE

Those who wanted to maintain a strategic nuclear balance
put emphasis on developing less-accurate, single large
warheads that would be unable to hit anything smaller
than area targets. Such missiles would be effective against
countervalue targets, which do not require precise accu-
(legend) to be effective; but would be less effective hitting silos
or airfields.

It was feared, however, that a number of innovations
and weapons systems could disrupt this strategic balance.
Such a disruption could lead one side to perceive a “win-
dow of opportunity” in which they would be tempted to
launch a preventive war before new technological innova-
tions either restored the balance or shifted first-strike
advantage to the opponent. For example, declarations of
“bomber gaps” or “missile gaps” by United States politi-
cians, particularly in the late 1950s and early 1960s, led
many to fear that (alleged) Soviet advantage could lead to
a devastating first strike. The development of multiple
independently targeted reentry vehicles (MIRVs), which
are intercontinental ballistic missiles (ICBMs) carrying
multiple warheads that can be individually programmed
to hit separate targets, was also seen as destabilizing, as one
missile could target multiple ICBM silos. This offensive
advantage, it was feared, could tempt one country to
launch a preemptive attack out of fear that it would suffer
a debilitating blow if it were not the one to attack first.

Another potential innovation capable of disrupting
strategic balance is some form of missile defense system.
While an effective missile defense system could protect a
country from nuclear annihilation, it would also provide it
with an overwhelming first-strike advantage, as its oppo-
nent would be unable to retaliate, regardless of the number
of surviving nuclear forces. There would also be an inen-
tive to strike sooner rather than later, as military history has
shown that all defenses are eventually penetrable.

Arms control agreements between the United States
and the Soviet Union during the Cold War were primarily
designed to stabilize the strategic balance between the two
sides. By limiting each side’s ability to gain first-strike
advantage, the hope was that neither side would be tempted
to carry out a preemptive first strike. The Anti-Ballistic
Missile (ABM) Treaty, Strategic Arms Limitation Talks
(SALT I and II), the Strategic Arms Reduction Treaties (START I and II), and the Strategic Offensive Reduction Treaty (SORT) were all designed to provide a framework in which the United States and the Soviet Union (now Russia) could maintain a nuclear balance without engaging in a costly and potentially dangerous arms race.

CURRENT CONCERNS AND FEARS
Since the end of the Cold War, fears of a nuclear exchange between the United States and Russia have subsided. However, a number of concerns still remain. India and Pakistan, which both officially declared their nuclear status with a series of tests in 1997, have a long history of conflict, specifically over the contested Kashmir region. This history of conflict, their contingent border, and an understated command and control system, make a nuclear exchange (either intentional or accidental) a very real possibility.

It is also feared that a “rogue” state could develop a nuclear weapon and be able to hold the world hostage by threatening to use it against a major world city if its demands were not met. While the world could easily retaliate if such a threat were carried out, the question remains whether there would be a willingness to risk giving up an important city in the first place. It is this potentiality that has led world leaders to take aggressive stances (with mixed success) against such potential proliferators as North Korea, Iraq, Iran, and Libya.

The final fear is that a terrorist organization would be able to acquire a nuclear device by stealing, buying, or being given it from a country’s arsenal. This is a particularly difficult scenario because normal countervalue threats would not have a very strong deterrent effect on a small, decentralized, apocalyptic terrorist organization.

WARREN, EARL
1891–1974
As the fourteenth Chief Justice of the United States, Earl Warren presided over a Supreme Court that handed down landmark rulings in the areas of race relations, school prayer, political representation, and criminal justice. Warren was born to Scandinavian immigrants in Los Angeles, California, on March 19, 1891. He was raised in Bakersfield, where his father worked for the Southern Pacific Railroad, and he himself worked a variety of summer jobs with the railroad. He put himself through school, earning both his undergraduate and law degrees at the University of California at Berkeley.

Warren began his political career as the district attorney of Alameda County, California. He went on to serve as California’s attorney general, and in 1942 he was elected governor. During his state service, Warren supported the evacuation of persons of Japanese ancestry from the West Coast during World War II. Throughout the remainder of his political career, Warren publicly defended his action, which stands in stark contrast to his role as one of the staunchest civil libertarians ever to serve on the U.S. Supreme Court.

Warren sought the Republican presidential nomination in 1948 and 1952. In 1948 he was chosen as Thomas Dewey’s running mate, but the Dewey–Warren ticket was defeated. In 1952, the Republican nomination, and the presidency, went to General Dwight D. Eisenhower. Following the unexpected death of Chief Justice Fred Vinson in the summer of 1953, President Eisenhower appointed Warren to fill the vacancy.

On the Supreme Court’s docket for the 1953 term was Brown v. Board of Education, a group of cases challenging the racial segregation of public primary and secondary schools. At the time, one-third of the states and the District of Columbia maintained segregated schools by law, often with vast disparities in school funding and facilities for black and white students. The Warren Court handed down a unanimous ruling in the Brown cases in May 1954, declaring that “separate educational facilities are inherently unequal.” A year later, in Brown II, the Court ordered that public schools be desegregated “with all deliberate speed.” In subsequent decisions, the Warren Court struck down racial segregation in public buildings, transportation, housing, and recreational facilities. The
Brown decisions were not the only Warren Court rulings that impacted public education. In Engel v. Vitale (1962) and Abington School District v. Schempp (1963), the Court ruled that state-sponsored prayer and Bible reading in public schools were establishments of religion in violation of the Constitution.

During the 1960s the Warren Court instituted a constitutional revolution in criminal justice. In a series of decisions, the Court used the Fourteenth Amendment to apply many of the guarantees of the Bill of Rights—the protections against self-incrimination and double jeopardy, the right to counsel, the right to a jury trial and to confront witnesses—to the states. Some of these protections were encapsulated in what became known as the Miranda warnings. According to the Court’s decision in Miranda v. Arizona, criminal suspects who are in custody must be informed of their constitutional rights, and they must waive those rights before any questioning may occur.

The Warren Court significantly altered the system of political representation in the United States as well. The first half of the twentieth century saw substantial population shifts from rural to urban areas, yet many state legislatures did not redraw representational districts to reflect these shifts. In a previous decision the Court had declined to address the apportionment issue, describing it as a “political thicket” that the Court should avoid. But in its 1962 ruling in Baker v. Carr, the Court rejected this reasoning, opening the door to a series of decisions establishing the “one person, one vote” principle for political representation and applying this principle at the congressional, state, and local levels. After leaving the Court, Warren described Baker v. Carr as the most important decision handed down during his tenure.

Warren resigned from the Court in 1969 and was replaced as Chief Justice by Warren E. Burger. He died on July 9, 1974, following a series of heart attacks, and was buried in Arlington National Cemetery.

WARREN REPORT

Warren Report is the abbreviated, unofficial name of the Report of the President’s Commission on the Assassination of President John F. Kennedy. This commission’s unofficial, commonly used name is the Warren Commission because it was chaired by Earl Warren, chief justice of the U.S. Supreme Court. President Kennedy was assassinated in Dallas, Texas, on November 22, 1963. President Lyndon B. Johnson established the Warren Commission on November 29, 1963. The Warren Report was published on September 27, 1964.

Shortly after Kennedy’s assassination, there was widespread speculation that Kennedy’s assassination was the result of a conspiracy, probably involving the Communist governments of Cuba and/or the Soviet Union. President Johnson was concerned that widely held conspiracy beliefs might undermine the legitimacy of the American presidency and detrimentally affect American foreign policy. Johnson hoped that a presidential commission that carefully investigated Kennedy’s assassination and published a well-researched conclusion would dismiss or discourage irresponsible, groundless, alternative explanations of Kennedy’s assassination. He assumed that the public credibility of the Warren Commission’s investigation and report depended on the objectivity, integrity, and expertise of the commission’s members.

Consequently, Johnson appointed Democrats and Republicans, current or former members of all three branches of the U.S. government, and senators and representatives to the commission. With Chief Justice Warren as its chairman, the commission also included Democratic Representative Hale Boggs of Louisiana, Republican Representative Gerald R. Ford of Michigan, former World Bank president and Kennedy adviser John McCloy, former CIA director Allen W. Dulles, Democratic Senator Richard Russell of Georgia, and Republican Senator John Sherman Cooper of Kentucky. During its ten-month investigation, the Warren Commission received testimony from 552 witnesses, reports from the FBI, CIA, Secret Service, and other federal agencies, tests on ballistics, and information from officials in Texas.

The major finding of the Warren Report was that Kennedy’s assassination was not the result of a conspiracy. The report found that Lee Harvey Oswald acted alone in killing Kennedy and wounding Governor John Connally of Texas. The report concluded that Oswald fired three bullets from the Texas School Book Depository. One bullet hit Kennedy in the back, went through his throat, and struck Connally. A second bullet fatally struck Kennedy in the head. A third bullet missed Kennedy’s car entirely.

The Warren Report also stated that there was no evidence to prove that there was a second gunman who shot at the motorcade from a different location. The report...
rejected the idea that Jack Ruby, who shot and killed Oswald shortly after Oswald's arrest, was part of a conspiracy to silence Oswald. Chapter 8 of the Warren Report detailed what the commission regarded as lax, inadequate, and outdated practices by the Secret Service in planning and protecting Kennedy's trip to Dallas. In particular, the report noted the Secret Service's use of its outdated security plan for Franklin D. Roosevelt's 1936 visit to Dallas as the basis for Kennedy's visit, its inadequate coordination with Dallas officials in planning and conducting security for Kennedy's visit, and the lack of a bulletproof cover for Kennedy's car in Dallas. The Secret Service also failed to thoroughly search all buildings, rooftops, and windows along the motorcade route before the motorcade began.

By the late 1960s, independent researchers and the American public increasingly doubted the findings of the Warren Report, especially its "lone gunman" and "single bullet" theories. The first two well-known books challenging the Warren Report were Edward J. Epstein's *Inquest* and Mark Lane's *Rush to Judgment*, both published in 1966. Lane's book was also made into a documentary. Epstein especially challenged the feasibility of the "single bullet" and "lone gunman" theories, and Lane asserted that Oswald did not assassinate Kennedy. In general, both books criticized the Warren Commission for intentionally ignoring or rejecting important evidence that threatened its anticonspiracy bias.

By the 1970s, with the Watergate scandals and Richard M. Nixon's forced resignation from the presidency, more Americans were willing to believe that government officials and agencies, especially the military, FBI, and CIA, engaged in conspiracies, cover-ups, and abuses of power. The congressional investigation of Watergate was followed by highly publicized congressional investigations of the FBI and CIA, including allegations that the CIA was connected to assassination conspiracies directed against foreign leaders. Most significantly, the 1979 report of the House Select Committee on Assassinations (HSCA) rejected part of the Warren Report and concluded that a total of four shots were fired, one of which was fired by a second gunman from Dealey Plaza's grassy knoll.

During the 1980s and 1990s, the number and variety of conspiracy theories rejecting the Warren Report increased. Some theorists claimed that Kennedy was killed by organized crime because gangsters were angry that Kennedy had betrayed them by allowing the Justice Department to vigorously prosecute them and by failing to overthrow Fidel Castro. Others asserted that wealthy, right-wing extremists in Texas hired assassins to kill the president. Oliver Stone's 1991 film *JFK*, based on Louisiana attorney James Garrison's investigation of Kennedy's assassination, implied that a government conspiracy that included the CIA, the military, and Johnson killed Kennedy.

Partially to refute this film, Gerald Posner researched and wrote *Case Closed: Lee Harvey Oswald and the Assassination of JFK* (1993). Posner criticized some of the Warren Commission's efforts as too hasty and incomplete, but he generally reaffirmed the Warren Report's conclusions, especially the "lone gunman" and "single bullet" theories. Shortly after Posner's book was published, Harold Weisberg countered with *Case Open: The Omissions, Distortions, and Falsifications of Case Closed* (1994), which rejected the Warren Report and Posner's defense of it. It is unlikely that there ever will be a definitive, widely shared public acceptance of the Warren Report.

**WARSAW PACT**

The Warsaw Pact was signed on May 14, 1955, in order to create an organization of Central and East European Communist states. It is different from the Warsaw Convention, signed in 1929, which is an international convention regulating liability for commercial airlines transporting persons, luggage, or goods.

The formal name of the Warsaw Pact was the Treaty of Friendship, Co-operation, and Mutual Assistance. It was created for two reasons: first, to counter the threat from the North Atlantic Treaty Organization (NATO), an alliance established six years earlier; and second, in reaction to the admission of West Germany into NATO. The initial members of the Warsaw Pact were the Soviet...
Union, Albania, Bulgaria, Czechoslovakia, East Germany, Hungary, Poland, and Romania. Yugoslavia was the only Communist state not to sign the treaty. Albania withdrew from the pact in 1968. Despite being initially created to counter the threat of NATO, in practice the pact was a tool of the Soviet Union, used to strengthen its hold over its satellite countries. In contrast to NATO, the Warsaw Pact was completely subordinated to a single power. The pact allowed the Soviet Union to impose its military and political agenda on Central and East European countries through the use of both its military and economic power. The pact was supposed to last for only twenty years and become void if any of the members decided to drop out. Nonetheless, the agreement was renewed in 1975 for another ten years, despite Albania’s unilateral withdrawal from it seven years earlier.

PRINCIPLES
The signatory parties of the Warsaw Pact agreed to abstain from violence or from the threat of violence in international relations. The treaty established the goals of the members, which included world peace and security, and global disarmament. Countries also had to confer with each other on matters of international affairs and agreed that in the event of outside aggression against one member, all member countries would defend the threatened country together. However, the Soviet Union also wanted to use the Warsaw Pact as a bargaining tool with non-Communist European countries. This is evidenced by the concluding article of the pact, which stipulated that the agreement would lapse in the event of an East-West collective security pact.

The treaty, signed in 1955, was supplemented by numerous bilateral treaties between the Soviet Union and satellite countries. Among other things, these treaties gave Soviet troops the right to be on the soil of signatory countries. Some countries, such as Poland, allowed the stationing of Soviet troops on their soil under the 1945 Potsdam Agreement and through a separate bilateral treaty. Hungary also had a bilateral agreement with the Soviet Union. Soviet troops prevented Hungary’s 1956 attempt to secede from the organization and crushed liberal movements in Czechoslovakia that emerged in what came to be known as the “Prague Spring.” Czechoslovakia only signed its bilateral treaty with the Soviet Union after the Soviet invasion and was essentially forced to accept the “Brezhnev Doctrine,” which limited the sovereignty of the Communist states and granted the right of Soviet intervention.

The extent to which the Soviet Union maintained a military presence in the satellite countries depended on its assessment of each individual member’s risk of defecting from the organization were it to be pressured to allow Soviet troops on its soil. Thus, when the bilateral agreement with Romania expired in 1958, it was not renewed, because of Romania’s wish to avoid the presence of Soviet troops, even for temporary purposes such as maneuvers. Soviet troops were stationed in Bulgaria, on the other hand, though only for temporary purposes, such as military exercises.

Even though the Warsaw Pact allowed for military alliances outside the Communist-bloc countries and functioned as an instrument of Soviet policy, it had no provisions concerning activities outside the European continent.

ORGANIZATION
The Political Consultative Committee (PCC) was the highest governing body of the Warsaw Treaty Organization. Its permanent members were the Communist Party’s first secretaries and the premiers and foreign ministers of member countries. The PCC had managerial authority over the cultural, political, and economic spheres of the entire organization. However, its most important function was deciding when a crisis met the criteria for executing the provisions of the military clauses. In practice, the PCC’s power could be limited, as shown by the 1968 invasion of Czechoslovakia, which was not decided on by the PCC.

The secretary general of the organization was always a Soviet general or Soviet foreign ministry official and control was always held in Moscow. The Committee of Defense Ministers (CDM), which decided on directives communicated to national defense planners in member nations, was subordinate to the PCC and was also located in Moscow.

THE END OF AN ERA
Even though NATO and the Warsaw Pact were created to counter each other’s dominance, the member countries never engaged each other in armed conflict, though they did engage in “proxy wars.” In December 1988, Mikhail Gorbachev, then leader of the Soviet Union, declared that the Brezhnev Doctrine would be abandoned and that the Soviet Union’s satellite countries could do as they wished. Soon after, a number of political changes swept across Central and Eastern Europe, leading to the end of Communism. After 1989 the Warsaw Pact started losing the support of its members. In January 1991, Czechoslovakia, Hungary, and Poland announced they would withdraw all support within six months. Bulgaria followed suit in February 1991. The Warsaw Pact was officially dissolved at a meeting in Prague on July 1, 1991.

WASHINGTON, GEORGE
1732–1799

George Washington was the first president of the United States of America. He was born in Westmoreland County, Virginia, on February 22, 1732. Washington's father, Augustine Washington, died in 1743 and his older half brother, Lawrence Washington (1718–1752), was subsequently responsible for George Washington's upbringing and training as a surveyor and tobacco planter. Lawrence also nurtured Washington's interest in military service.

Partially because of his protégé relationship with Thomas Fairfax (1691–1782), a Virginia planter influential with British nobility, and his replacement of Lawrence as district adjutant in 1752, Washington was promoted to the rank of colonel in the Virginia militia in 1754. Shortly before the outbreak of the French and Indian War (1756–1763), Washington led a military expedition to the westernmost boundaries of Virginia because French troops and their Indian allies threatened British-claimed territory. He ordered his men to build Fort Necessity in this area but soon abandoned the fort because of superior French and Indian forces in 1754. After the arrival of British troops, Washington became an aide to British general Edward Braddock (1695–1755). Washington distinguished himself in combat, especially in the campaign against Fort Duquesne, and was elected to Virginia's House of Burgesses in 1758.

In 1759 Washington married Martha Custis (1731–1802), a wealthy widow, and increased his ownership of land and slaves. He was active in local politics, but he mostly focused on his agricultural and financial interests. Washington had admired Britain's army, aristocracy, and mixed system of government since childhood. But he gradually concluded during the 1760s and early 1770s that new British taxes and regulations reflected “taxation without representation” and their implementation by British troops and officials increasingly violated Americans' legal rights as British subjects. While he was occasionally disturbed by the more extreme rhetoric and behavior of revolutionary leaders in Boston, Washington eventually became committed to the cause of rebellion and then independence. He concluded that the American colonies must become a separate nation in order to protect their liberty, self-government, and economic interests.

In 1774 Washington was elected as a delegate to the first Continental Congress. John Adams (1735–1826), a delegate from Massachusetts, became acquainted with Washington. Adams was impressed by Washington's military service and political status in Virginia. Wanting to increase national, and especially southern, support for the American Revolution against Britain, Adams secured Washington's appointment as general and commander-in-chief of the Continental Army in 1775. Washington then traveled to Massachusetts and assumed command on July 3, 1775. After placing artillery to threaten British ships in Boston Harbor, Washington forced the British to evacuate Boston on March 17, 1776.

Until the British surrender at Yorktown, Virginia, in 1781, Washington's strategy was to continue the American military and political effort until the British government decided to end the war as too costly. Washington generally avoided large-scale, prolonged battles and relied on surprise attacks, like the Battle of Trenton (1776), and tactical retreats to limit American casualties. During the Revolutionary War, Washington gained a national reputation among Americans for his endurance, integrity, and strength of character in the cause for independence. He struggled to maintain discipline, order, and professional military standards among American troops. Although Washington was critical of Congress for not providing enough pay and supplies for his troops, he always yielded to Congress's civilian supremacy over his military command. After the Treaty of Paris officially ended the war in 1783, Washington voluntarily surrendered his commission as commander-in-chief to Congress and returned to Mount Vernon, his plantation in Virginia.

After the Revolutionary War, Washington struggled to improve his neglected finances. Like other planters, however, Washington suffered from the disruption of prewar trading relationships with the British Empire, high inflation, and trade barriers that states imposed against each other. The weak national government of the Articles of Confederation was unable to solve or alleviate these economic problems. Washington was also troubled by Shays's Rebellion in Massachusetts in 1786 and other events that indicated that the nation might dissolve into anarchy, disunity, and political radicalism.

In his personal life, Washington had no legally recognized children, although he may have fathered a child with Venus, his half brother's slave. He was an Anglican (or Episcopalian) but was not a frequent churchgoer. Like many upper-class Americans in the late eighteenth century, Washington was a deist who perceived God to be...
impersonal and rational. Nevertheless, his private and public statements reveal his belief that God, or Providence, had a special destiny for the American nation. Later in his life, Washington expressed the need for religion to promote civic virtue.

Washington was known for treating his slaves more humanely than other slave owners. He encouraged marriage among his slaves and refused to break up slave families by selling them to other planters or investing in the “breeding” of slaves. As he became older, Washington became more troubled by the moral dilemma and economic burden of slave ownership. Nonetheless, Washington accepted the institution of slavery, and his wife inherited his slaves after his death.

Washington reluctantly returned to public life and was elected as a Virginia delegate to the Constitutional Convention in Philadelphia in 1787. Washington's fellow delegates unanimously elected him to preside at the convention. As president of the convention, Washington maintained order during the debates and rarely expressed his political opinions. Washington's judicious reticence further enhanced his reputation among delegates as a dignified, virtuous, self-restrained national leader who could be entrusted with executive power. Alexander Hamilton (1755/57–1804) was a delegate from New York who served as a staff officer for Washington during the war and revered him. Hamilton shrewdly promoted the common assumption that Washington would be the first president in order to gain delegate support and later ratification for the strong presidency that he explained and advocated in *The Federalist Papers*.

George Washington was unanimously elected president in 1789 and inaugurated in New York City, the nation's first capital under the Constitution. John Adams was elected vice president, and Washington's first cabinet included Thomas Jefferson (1743–1826) as secretary of state and Alexander Hamilton as secretary of the treasury. Washington was unanimously reelected in 1792 and inaugurated in Philadelphia in 1793. He disliked the growing partisan and policy conflicts between the Federalists and Anti-Federalists, especially between Hamilton and Jefferson, and warned the nation of the dangers of partisanship in his farewell address of 1796. Washington struggled to be nonpartisan during his first term but became a Federalist during his second term, partially because of the criticism of his presidency and policies from Anti-Federalist newspapers and politicians.

George Washington's interpretation and use of presidential powers established several important precedents for the American presidency. First, Washington established the belief that a president should limit himself to two terms of office, a practice that continued until President Franklin D. Roosevelt (1882–1945) was elected to a third term in 1940. The Constitution was amended in 1951 to formally limit a president to two elected terms. Washington had previously rejected the suggestion that he be appointed as a monarch or president with a life term of office. He later rejected a request that he run for a third term.

Second, Washington believed that a president should only veto bills that he regarded as unconstitutional. Consequently, he vetoed only two bills during his presidency. It was not until the presidency (1829–1837) of Andrew Jackson (1767–1845) that a president actively vetoed bills because of political or policy differences with Congress.

Third, while Washington believed that a president should be self-restrained and generally defer to Congress on domestic legislation, he also asserted that a president should exercise more discretionary and dominant power in foreign and defense policies. He interpreted the president's power to “receive Ambassadors” in Article II of the Constitution to mean that the president alone can decide whether to recognize a new foreign government as legitimate for a regular diplomatic relationship with the U.S. government. Fourth, after a frustrating experience with the Senate in negotiating a treaty with the Creek Indians, Washington began the precedent of a president initiating and conducting treaty negotiations and only seeking the Senate's “advice and consent” afterward for ratification. Likewise, he refused to provide diplomatic correspondence pertaining to the Jay Treaty to the House of Representatives because the Constitution did not require him to do so. This was an early example of executive privilege, that is, the president's limited, unwritten constitutional right to withhold information from Congress.

Washington also developed the president's symbolic role as the head of state who represents all Americans both nationally and internationally. He contributed to this role by occasionally visiting the various states and issuing proclamations. He proclaimed Thanksgiving as a national holiday in 1789. More importantly, he proclaimed American neutrality between the warring governments of Britain and France in 1793. Washington also insisted that all of his cabinet members publicly support his policies. For example, Washington forced the resignation of Secretary of State Edmund Randolph (1753–1813) in 1795 because he suspected Randolph of being pro-French, despite American neutrality.

Although Washington usually deferred to Congress on domestic legislation, he relied on Alexander Hamilton, his first secretary of the treasury and closest adviser, to formulate and promote legislative passage of his economic program, which included a national bank, a hard currency, and tariffs and excise taxes to liquidate Revolutionary War debts and provide adequate revenue to
maintain a national army. Because of Article II’s “take care” clause, Washington believed that a president should exercise broad, discretionary powers to enforce federal laws. This belief was especially evident in Washington’s firm, decisive suppression of the Whiskey Rebellion of 1794. Washington personally led troops during part of their expedition to western Pennsylvania to end mob violence against the collection of the federal excise tax on whiskey.

Despite the efforts of Hamilton to persuade Washington to remain in office, Washington publicized his farewell address on September 19, 1796. In addition to warning the public about how partisan conflict threatened liberty, order, civic virtue, and national unity, Washington stated that future American foreign policy must continue to avoid “permanent alliances” with foreign governments that endangered American independence, liberty, and peace. Shortly after John Adams was inaugurated as president on March 4, 1797, Washington returned to Mount Vernon.

During his retirement, Washington busied himself with improving his finances and repairing buildings on his plantation. In 1798 Washington accepted a commission as a lieutenant general from President Adams and the Senate. He avoided public statements on politics and refused to undermine Adams’s authority as president. He was dismayed that the Federalist Party became bitterly divided between pro-Adams and pro-Hamilton factions and that war with France seemed more likely.

Washington returned home after inspecting his fields on December 12, 1799, and became ill with a severe cold. Further weakened by the use of bloodletting as a medical treatment, Washington died on December 14, 1799. General Henry Lee’s (1756–1818) funeral oration, delivered before Congress on December 26, 1799, popularized Washington’s historical and patriotic reputation as “the father of his country.” The nation’s capital city was named after Washington, as were many towns, counties, schools, and a state. The most nationally prominent artistic dedications to George Washington include the Washington Monument in Washington, D.C., and an enormous sculpture of his face on Mount Rushmore in South Dakota. His birthday was celebrated as a separate national holiday but was more recently incorporated as part of Presidents’ Day in February.

**WASHINGTON CONSENSUS**

The phrase *Washington Consensus* has come to refer to a neoliberal economic agenda for developing countries and carriers the implication that the Washington, D.C.–based public organizations that agree on the appropriateness of this agenda. Neoliberal refers to the ideas about the virtues of free markets and small, regulatory states emanating from the Mont Pelerin Society and developed primarily by Milton Friedman and Friedrich von Hayek, and to some extent implemented by Ronald Reagan, Margaret Thatcher, Augusto Pinochet, and the New Zealand Labour government during the 1980s.

The phrase had more modest beginnings. It was coined in a 1990 article by the British economist John Williamson, who had spent years working in a Washington, D.C., think tank, the Institute for International Economics. Williamson noticed that during the second half of the 1980s Latin American countries experienced a major change in economic policy norms. Previously, Latin American governments tended to think that import substitution, state enterprises, and inflationary finance constituted the core of development strategy, and that macroeconomic stabilization, free trade, and a framework-providing state were only appropriate for the already-developed countries. In the wake of the 1980s debt crises, both Latin American governments and the Washington organizations “saw the light” and concluded that what was appropriate for the developed countries was also appropriate for them.

Williamson’s list of what he considered to be generally accepted policy priorities in Washington and in Latin America by the late 1980s included the following:

1. **Keep budget deficits small.**

2. **Shift public expenditure priorities from non-merit subsidies to expenditures that are pro-growth and pro-poor, like spending on basic health, education, and infrastructure.**

3. **Construct a tax system that combines a broad tax base with moderate marginal tax rates.**
4. Liberalize interest rates (meaning that while independent central banks should fix the base rate, commercial lenders should be free to set whatever the market can bear on top of base rate).
5. Maintain a competitive exchange rate via an “intermediate” regime, between fixed and free-floating.
7. Liberalize inward foreign direct investment—but without pursuing comprehensive capital account liberalization.
8. Privatize state enterprises.
9. Ease sectoral barriers to entry and exit.
10. Provide the informal sector with the ability to gain property rights at acceptable cost.

After Williamson published his list, champions of neoliberalism deployed the phrase Washington Consensus for their own purposes. They detached it from Williamson’s policy list by adding elements like low taxes, a minimal state, and rapid liberalization of cross-border financial flows (“opening the capital account”). They also detached it from its regional origin, implying that it applied to all developing countries, including those “in transition” from socialism to capitalism. In this newly fundamentalist form it coursed through the echo chamber of the Washington-based organizations, including the International Monetary Fund, the World Bank, the U.S. Treasury, USAID, and think tanks; through transatlantic components including The Financial Times, The Economist, and the U.K. Treasury; and into finance and development ministries in many developing countries.

“Stabilize, deregulate, open up, and privatize” became the slogan of technocrats and political leaders through the 1980s, and it inspired a wave of reforms that had transformed the policy landscape of much of the developing world by the early 1990s. The common denominator was the drive to extend private property rights geographically and “vertically,” to types of assets not previously privately owned, and in this way expand profit opportunities for global firms facing declining profits at home. The reforms accelerated the “financialization” of the world economy and the shrinkage of the economic sovereignty of the state. Yet economic performance of most developing countries remained disappointing. Many countries that adopted this approach to a high degree had worse performance than during the era of “bad” import-substituting industrialization, and worse performance than those that adopted it to a small degree. In particular, many countries that followed the neoliberal prescription of “economic growth with foreign savings”—which entailed opening the economy to free flows of finance—were hit by financial crises through the 1990s.

In response a new consensus, sometimes called the Augmented Washington Consensus, began to emerge by the mid-1990s (see Williamson 2003). It said that neoliberal policies would not have lasting effects where institutions were unfriendly to markets, an argument in line with the major thrust in development economics over the 1990s to assert the role of institutions in affecting transaction costs and thereby economic performance. “Get the prices right” had to be supplemented with “get the institutions right.” The new “good governance” agenda called for reforms in the civil service (the budget office, the central bank, the customs bureaucracy), the judiciary, the financial sector (the accountancy profession, the rights of minority shareholders, credit registries), systems of primary education and primary healthcare, and microcredit.

The Augmented Washington Consensus retained the neoliberal premise that the state was the problem and the market the solution, and the aim was to make markets work better and to extend surrogate markets into the state. The word reform was reserved for changes in this direction. Many champions hoped that financial reforms would strengthen regulation sufficiently so that opening the capital account could again become a top global priority. Issues of equity, income distribution, technology, firm-level capabilities, and industrial policy remained firmly off the radar screen.

However by the late 1990s some parts of the “international development community,” notably the United Nations’ General Assembly and the United Nations Development Programme (UNDP), began to unite around an action agenda that emphasized poverty reduction and investment in primary health and primary education. This perspective was spelled out in the Millennium Declaration and in the Millennium Development Goals adopted by the UN in 2000. Critics of neoliberalism took advantage of the new discussion to declare that the Washington Consensus was dead and had been replaced by a “Post Washington Consensus Consensus,” which held that “countries should be given scope to experiment, to use their own judgment, to explore what might work best for them” (Stiglitz 2004, p. 12).

A more open-minded stance toward policy experimentation is surely a good thing. But pragmatism is not a strategy. At the operational levels of the Washington-based organizations and in the most powerful agencies in developing countries—finance ministries as distinct from development ministries—the Washington Consensus is far from dead, if only because nothing coherent has emerged to replace it. Development technocrats find it a huge advantage to be able to use the Washington Consensus one-size-fits-all approach; whatever the coun-
try, they know what the government should be doing. Certainly the Millennium Development Goals are an add-on rather than an alternative because they assume that the core microeconomic reforms of the Washington Consensus are necessary conditions for achieving the goals. In short, reports of the death of the Washington Consensus are greatly exaggerated, whether for better or for worse.

WATER RESOURCES

The planet Earth is inherently short of freshwater, the proportion of which is as little as 3 percent of all available water. The remaining 97 percent of water is saline and is stored in the oceans. Of the 3 percent of water that is freshwater, only 0.3 percent flows through surface water systems such as rivers and lakes; the remaining 2.97 percent is frozen in glaciers and ice caps or held in the ground.

This inherent scarcity has been worsened by the accelerated diversion of water for agricultural, commercial, industrial, and residential uses, which has increased greatly in response to a growing world population that reached 6.5 billion people in 2006. As much as 95 percent of that growth has taken place in the water-deficit developing world, predominantly in Asia and Africa. Among all human uses, agriculture tends to use 70 percent of the available freshwater. According to experts, 1 ton of grain requires 1,000 tons of water. As agriculture increasingly is becoming dependent on irrigation, especially in Asia, the most populous continent, the availability of water for industrial, commercial, and municipal uses has been shrinking.

WATER SCARCITY AND THE HUMAN CONDITION

The impact of dwindling water supplies on humankind is evident worldwide. According to a 2006 report by the United Nations Development Program, over 1 billion people are without clean drinking water and over 2.4 billion lack basic sanitation. Access to clean drinking water is lowest in Africa, and Asia has the largest number of people without basic sanitation. The human toll of the inaccessibility of water and sanitation runs as high as 2 million child deaths a year (United Nations Development Program 2006). In all, in the early years of the twenty-first century 12 million people died each year from drinking contaminated water.

In 2003 the United Nations World Water Development Report estimated that $110 billion to $180 billion would be needed each year to provide safe drinking water to the poor in developing countries. Although an annual outlay of that size for water resource development seems prohibitive for low-income nations, the economic benefits of such an outlay would be two to three times as large. Recognizing those benefits, the United Nations Millennium Development Project planned to widen the access of the poor to safe drinking water by 50 percent by 2015. The economic benefits of increased access to safe drinking water in terms of health, longevity, and time saved in fetching water range from $300 billion to $400 billion a year.

PRICING AND PRIVATIZATION OF WATER

International development agencies such as the World Bank and the Asian Development Bank (ADB) plan to broaden the access of the poor to safe water by pricing water use and privatizing water resources. Water pricing means consumers will pay the fees, taxes, or charges for water supplies they use. It has been argued that water privatization can meet the water needs of the poor effectively. In 2005 Segerfeldt pointed out that public water systems in developing countries tend to serve wealthy and middle-class households, whereas the poor are left to draw from municipal water mains. However, 80 percent of the poorest parts of the population in fifteen developing countries are not served by municipal water supplies (Segerfeldt 2005). Although privatization is intended to bring the entire water supplies and treatment systems of developing countries into the private market, in the first decade of the twenty-first century only 3 percent of the poor worldwide were served by private-sector water supplies.

Critics see water privatization as a “global water grab” with disastrous outcomes in places such as Cochabamba, Bolivia. Between 1989 and 1999 the proportion of Bolivian households connected to the public water system
fell from 70 percent to 60 percent. Water was available only sporadically; 99 percent of the wealthier households were receiving the subsidized water, whereas in some poorer suburbs less than 4 percent were receiving water.

FATE OF PRIVATIZATION IN INDIA AND CHINA

In 2002 Vandana Shiva blamed the World Bank and the ADB for creating water markets to benefit multinational corporations (MNCs). Privatization, she argued, is preceded by a hike in water tariffs to “secure private sector investment in risky countries” (Shiva 2005). The tariff increase, Shiva asserted, exceeds by ten times the “full cost recovery,” although this is rationalized by privatization supporters. Using the case of her native India, Shiva stated that private operators will harvest public investment of 1 trillion rupees for private gains through water privatization in India (Shiva 2005).

Pricing and privatization of water are intended to rationalize water use. In light of worldwide extreme income inequalities, however, it is feared that privatization will save water by diverting it from the poor to the rich and from rural areas to urban centers. In 2005 Shiva argued that the best way to conserve water is to make a radical shift from water-intensive chemical farming to organic farming, along with a reversal in export-led agricultural production, which amounts to exporting “virtual water” to the rich consumers of the North at the expense of the poor in the South.

Like India, China is poor in freshwater supplies, the per capita availability of which is one-fourth of the world average (Yu and Danqing 2006). The pollution of rivers and groundwater from industrialization and urbanization has exacerbated the water shortage. In the first decade of the twenty-first century, two-thirds of Chinese cities had an insufficient supply of freshwater and 110 of them had critically inadequate access to freshwater.

Beijing’s plan to meet the water needs of urban centers angered Chinese rural residents. On July 6, 2000, thousands of farmers in the Yellow River Basin in eastern China clashed with police over a government plan to recapture runoff from a local reservoir for cities, industries, and other uses (Postel and Wolf 2001). The incident took place in Shandong, the last province through which the Yellow River runs before reaching the sea. Worldwide water disputes have been occurring in the downstream regions of overtapped river basins (Postel and Wolf 2001). The Yellow River has been running dry in its lower reaches on and off since 1972, and its dry spell grew to a record 226 days in 1997. As a result, per person use of water in China, which already was severely low, fell by 1.7 percent in seven years (Yu and Danqing 2006).

WATER CONFLICTS

The Indus Basin Intrastate water shortages have spilled over into interstate water conflicts. In the first decade of the twenty-first century India and Bangladesh were worrying about alleged Chinese attempts to divert the waters of Yarlung Zangbo River (which in India is called Brahmaputra, and in Bangladesh Jamuna) into the Yellow River. The Yarlung Zangbo passes through the Tibet Autonomous Region into the Indian states of Arunachal Pradesh and Assam and into Bangladesh. Even starker conflicts have been simmering between India and Pakistan over the Ganges River and between India and Pakistan over the Jhelum River. In the 1960s and early 1970s India unilaterally constructed a barrage (dam) on the Ganges River at Farakka, near the border with Bangladesh, to divert more river water to the port of Calcutta (Postel and Wolf 2001). That diversion left Bangladesh with significantly less water for irrigation during the dry season, causing increased migration of its population across the border into the Indian states of West Bengal (Postel and Wolf 2001) and Assam. Although the Indus River Basin Treaty between India and Pakistan of the 1960s has held, the growing water and power needs of each nation are fueling the conflicts as never before. The major conflict between Islamabad and New Delhi has erupted over the controversial construction of Bhagliar Dam over the Jhelum River in the disputed territory of Jammu and Kashmir; that conflict was being arbitrated by the World Bank.

Euphrates and Jordan River Basins Euphrates and Jordan River Basin nations have long argued over their shared surface water systems. Syria and Iraq experienced a reduction of almost 50 percent in the average flow of the Euphrates after the 1970s (Allan 1998). Both countries have been anticipating additional reductions in the flow of Tigris as well. The Euphrates and Tigris rivers originate in Turkey, which has diverted their water by building dams. In the case of the Jordan basin, the river system rises in four tributaries (Lowi 1995): the Yarmouk in Syria, the Banias in Israeli-occupied Syria, the Hasbani in Lebanon, and the Dan in Israel. The Banias, Hasbani, and Dan meet in northern Israel to form the Upper Jordan River, which flows into Lake Tiberias, and then the Lower Jordan. Israel has become the upstream riparian basin on the Upper Jordan system, and Syria is upstream on the Yarmouk. Jordan and the Palestinians, as downstream riparian basins vis-à-vis both Israel and Syria, have remained in the worst positions in the basin (Lowi 1995).

About one-half of Israel’s annual supply of groundwater and one-quarter of its total renewable supply of freshwater originate in two subterranean basins in the West Bank (Lowi 1995). By virtue of its occupation of the West
Bank, Israel has been controlling water in the territory. The result has been that approximately 80 percent of West Bank water is exploited in Israel and by Israeli settlers in the territory, leaving only 20 percent for the Palestinian population (Lowi 1995). Although Lowi does not think that water disputes alone could cause active conflict between Israel and the countries of the Jordan River Basin, Adel Darwish (2003) and John Bulloch and Darwish (1993) believe that water disputes underlie the political conflict in the region. King Hussein of Jordan and the late Egyptian President Anwar Sadat, each of whom signed peace treaties with Israel, vowed never to go to war with Israel except to protect water resources (Darwish 2003). Bulloch and Darwish (1993) claim that water was the hidden agenda for past conflicts and has been a major obstacle to a lasting peace in the region. The Six Day War, they argue, started because Syrian engineers were working to divert part of the water flow from Israel. The Israeli leader Ariel Sharon backed up their argument by saying: “People generally regard 5 June 1967 as the day the Six-day war began. That is the official date. But, in reality, it started two and a half years earlier, on the day Israel decided to act against the diversion of the Jordan” (quoted in Darwish 2003).

POSSIBLE SOLUTIONS

It is feared that global warming will cause further stress in the already water-short nations of Asia, Africa, and the Middle East. Although bilateral and multilateral water-sharing mechanisms are important to ensure critical water supplies, the significance of conservation and further development of water resources cannot be overemphasized. There are a number of technological means to augment water resources, including but not limited to cloud seeding, desalination, wastewater reuse, rain harvesting, and importing water from relatively wet zones (Postel and Wolf 2001). Of equal importance are a shift from water-intensive chemical farming to less water-intensive farming methods and a reversal in export-led agricultural production, which amounts to the export of virtual water from the water-short South to the water-surplus North (Shiva 2005).

WATERGATE

The Watergate scandal involved Richard M. Nixon (1913–1994) during his second term as president of the United States. The scandal led to his impeachment and resignation from office.

In June 1971 a former employee of the U.S. Department of Defense, Daniel Ellsberg, gave The New York Times a secret government history of the Vietnam War (1957–1975) known as the Pentagon Papers. These revealed, among other things, a secret bombing campaign against neutral Cambodia. The White House issued an injunction against publication on the grounds of national security, but the injunction was declared unconstitutional by the U.S. Supreme Court, which saw it as a form of prior restraint in violation of the First Amendment. In response, Nixon directed aides to find damaging information about his perceived political enemies. By September 1971, a special investigative group known as “the plumbers” was hired by Nixon’s assistant for domestic affairs, John Erlichman, to burglarize the office of Ellsberg’s psychiatrist, which was located in the Watergate office complex in Washington, D.C.
On the night of June 17, 1972, a security guard working at the Watergate Hotel noticed a piece of tape between the door of the basement and the parking garage. Upon investigation by the Washington police, five men were discovered and arrested for breaking into the headquarters of the Democratic National Committee, located in the Watergate complex, in a failed attempt to place listening devices and take photographs of committee documents. Later, one of the burglars, James W. McCord Jr., was found to be in possession of phone numbers belonging to E. Howard Hunt (1918–2007) and G. Gordon Liddy, former employees of Nixon's reelection committee. At his arraignment, McCord identified himself as a former employee of the Central Intelligence Agency.

In attendance on the day of McCord's arraignment were Washington Post reporters Bob Woodward and Carl Bernstein, who began what became one of the most significant journalistic investigations of the twentieth century. A then-unknown individual with close ties to the White House, dubbed Deep Throat by Woodward, provided the journalists with information and assistance that helped them follow the story from an insignificant burglary to a cover-up orchestrated by the Nixon administration. Thirty years later, Deep Throat's identity was revealed when former FBI agent Mark Felt admitted that he had been Woodward's source.

In 1972 the Federal Bureau of Investigation established that the Watergate Hotel break-in stemmed from a spying effort conducted on behalf of the Nixon reelection effort. Despite this finding, Nixon won reelection in a landslide over the Democratic candidate Senator George McGovern in November 1972. By January 1973, however, the original burglars, along with Hunt and Liddy, went to trial, pleading guilty in a failed attempt to shield those above them from further inquiry. When the presiding judge, John Sirica (1905–1992), threatened thirty-year sentences, the defendants began cooperating with the prosecution. As the investigation broadened, the U.S. Senate established a committee, chaired by Senator Sam Ervin (1896–1985), to investigate the Watergate break-in.

By May 1973 two of Nixon's White House aides, H. R. Haldeman (1926–1993) and John Ehrlichman (1925–1999), resigned amidst growing evidence of their knowledge of the events. Both would later go to prison for their role in the Watergate break-in and cover-up. The Watergate hearings were broadcast live on television from May to August 1973, and were immensely popular, with dire consequence for the Nixon administration's approval ratings. As a result of these investigations, it was revealed that Nixon had recorded all his phone calls and conversations in the Oval Office. When Congress requested these tapes as part of the investigation, the president refused to turn them over. In an attempt to save himself from further political embarrassment and possible criminal indictment, Nixon directed Attorney General Elliot Richardson (1920–1999) to instruct special counsel Archibald Cox (1912–2004) to drop the subpoena for the White House tapes. When Cox refused, Nixon ordered Richardson to fire Cox. When the attorney general refused, Nixon fired both Richardson and his deputy in what is now known as the “Saturday night massacre.” A young solicitor with the attorney general's office, Robert Bork, assumed the role of attorney general. Bork then fired Cox, but was pressured to name another prosecutor, Leon Jaworski (1905–1982).

Citing executive privilege, Nixon refused to comply with the subpoena for the White House tapes, creating a constitutional conflict between the president and Congress. In July 1974 the U.S. Supreme Court unanimously ruled, in United States v. Nixon, that the president had to turn over the tapes to the committee. According to the Court, the president had no "unqualified" privilege of immunity. Less than one week later, a review of the tapes proved Nixon's role in the conspiracy to cover up the Watergate break-in. On one tape, Nixon and Haldeman, the White House chief of staff, directed the CIA to obstruct the FBI and the Justice Department's investigation into the break-in. It then became clear that the president and his aides had broken the law by orchestrating a cover-up, using the CIA to block the FBI investigation, lying to Congress, and destroying documents related to the investigation. Another scandal erupted when it was disclosed that an eighteen-minute gap had been found on one of Nixon's tapes. The gap was explained as an accident by Rose Mary Woods (1917–2005), Nixon's secretary.

In July 1974 the House Judiciary Committee passed the first of three articles of impeachment against the president for obstruction of justice, abuse of power, and contempt of Congress. Two additional articles of impeachment did not pass the committee: one for federal income tax evasion, and another for the authorization and subsequent concealment from Congress of American bombing operations in Cambodia. Throughout the ordeal, Nixon steadfastly proclaimed his innocence. On August 8, 1974, after consulting prominent members of Congress on the likelihood of the committee indictment being affirmed by the full House, Nixon became the first U.S. president to resign from office. Vice President Gerald R. Ford (1913–2006) assumed the presidency. Ford pardoned Nixon of all charges related to the Watergate break-in and cover-up on September 8, 1974.

In the aftermath of the Watergate affair, the media became more confident and aggressive in their coverage of Washington politics. Investigative journalists began looking into the public and private lives of politicians as never before. As a result, there have been numerous "gates" since Watergate, each referring to another scandal at the highest
levels of government. Additionally, Congress passed numerous “good government” bills in the years following the Watergate scandal. These addressed such issues as campaign finance reform, disclosure of campaign contributors and expenses to the Federal Election Commission, ethics in government, and a greater role for Congress in the appointment of independent counsels. Nixon continued to proclaim his innocence in the Watergate affair until his death in April 1994.

WEALTH
Throughout their history, human beings have been trying to improve the conditions of their existence. Ever since their early days, they sought to understand nature and dominate it. They discovered tools, salt, and fire, all of which made life better and easier. Possession of these “things” became a necessity. Wealth then meant all the things that are useful for satisfying needs and ensuring the well-being of their holder. This way of understanding wealth has not changed very much, for even today the Merriam-Webster Collegiate Dictionary defines wealth as “the stock of useful goods having economic value in existence at any one time,” or to be more precise: “All property that has a money value or an exchangeable value.” The modern definition reflects the popular understanding that wealth is synonymous with the acquisition and accumulation of real (physical) and financial assets. Material wealth, it seems, has always been important in the lives of individuals, from ancient to modern societies.

However, history of economic thought tells us that early civilizations in Mesopotamia, Egypt, and Greece had a positive attitude to knowledge, and many philosophers regarded it as the basis for wealth and empowerment. All the achievements in terms of progress (technical and other) were the result of the skills acquired through knowledge. The “light of fire” was a reflection of the “light of thought.” Modern economic theory also recognizes what we call “human capital” (health, education, and knowledge in general) is an important element of wealth. The subtlety of the modern view is that wealth is not only created—it is also inherited. Because wealth can often be transferred from parents to heirs without impediments, some rich people may not be particularly knowledgeable and some great minds may not be particularly rich. People naturally reject poverty and have a desire to get rich and live comfortably. Therefore, not only will they question the unequal distribution of wealth, they will also try—by whatever means available—to change the status quo. Poverty makes people feel oppressed, disobedient, difficult to govern, and ready for revolt. The extremists would claim that a life of deprivation is not worth living. Tensions over the distribution of wealth existed even in ancient societies. Class struggle, according to Karl Marx ([1867–1910] 1956), is a dynamic force of change in all class societies.

ORIGIN AND EVOLUTION OF THE CONCEPT
In ancient societies, when human needs were basic and wealth meant getting the goods from nature to satisfy their “natural” needs, there were no quarrels about being or wanting to be rich. Increased wealth simply translated into increased consumption and improved well-being. Wealth was necessary and everyone approved of it. Social values encouraged the ability to gather and/or produce more goods. The consensus came to an end when the distinction could be made between what was necessary (natural) and what had become luxurious or superfluous.
Luxurious consumption, which could be afforded by only some people, was condemned on moral and religious grounds as waste, ostentation, or vanity. The desire for luxury, it was argued, has no limits and requires excessive riches. In turn, the pursuit of excessive wealth makes people selfish, greedy, dishonest, and morally corrupt. The rise of private property is justified by the need to ensure continuous control over the flow of resources or goods that satisfy these needs, whether natural or artificial. Greek philosophers such as Plato and Aristotle opposed both extreme poverty and excessive wealth. Poverty was considered by most as a debilitating state, whereas the desire for excessive wealth led to a state of unhappiness. To avoid these extremes, many philosophers recommended moderation. The ideal state of well-being is that where the individual learns how to control and limit his or her desires and needs. Wealth therefore became associated with wisdom and virtue. The same idea was later integrated into religious thought as “the wealth of the soul”; an inner dimension that can be achieved through moderate use of material wealth. (For an excellent review of the ancient thought on the subject, see Perrotta 2003.)

However, as pointed out by Cosimo Perrotta, even though many ancient thinkers praised modesty and the simple, natural lifestyle, most would still prefer wealth and reject poverty. Material wealth, after all, “contributes to the life according to nature” (Perrotta 2003, p. 210). The rejection of poverty is also found in ancient eastern civilizations. For instance, ancient Indian thinkers believed that life on earth was only a transitory state, but they still wanted it to be a good life; an opportunity to “perform good deeds” and achieve “prosperity on earth.” According to Balbir Sihag, “[a]ncient thinkers in India put heavy emphasis on keeping a proper balance between spiritual health and material health” (2005, p. 2). Chanakya Kautiya, one of India’s ancient thinkers and a contemporary of Aristotle, “considered poverty as a living death and concentrated on devising economic policies to achieve salvation from poverty without compromising with ethical values” (Sihag 2005, p. 1).

Islamic thought did not consecrate poverty either. It advocated the circulation of wealth through voluntary alms giving, sadaqa, and required giving, zakat, from the rich to the poor. In fact, Arabs, both before and after Islam, believed that wealth included a part that must be given away. In Islam, the poor and the needy have a claim on, a recognized right to, a portion of the property of the rich. The Qur’an refers to the community of the believers as “those upon whose wealth there is a recognized right for the beggar and the deprived” (surat 70: 24–25). Based on this philosophy, the Muslims sought to build a “community that regulates its flow of money and goods in the right direction … that practices generosity as reciprocation for God’s bounty, that observes the haqq [i.e., the recognized right] inhering in the good things of this world, that purifies and maintains its wealth by giving up a portion of it in alms, and that takes ample account of the kinsman as well as … the poor stranger” (Bonner 2005, p. 404). The final goal is to achieve a virtuous life on earth—the moral well-being that the ancient Indian thinkers talked about.

MODERN VIEWS

The idea that wealth must be shared equitably was also expressed later by modern thinkers such as Adam Smith, Marx, and John Maynard Keynes. Smith, for instance, considered the unequal distribution of wealth as “the great and most universal cause of the corruption of our moral sentiments” ([1776] 1976b, p. 61). Smith defined wealth in terms of production of goods and services for the purpose of satisfying the needs of society as a whole. He argued that because workers are the main factor of production, they should have their fair share: “[n]o society can surely be flourishing and happy, of which the far greater part of the members are poor and miserable. It is but equity, besides, that they who feed, cloath and lodge the whole body of the people, should have a share of the produce of their own labor as to be themselves tolerably well fed, cloathed and lodged” ([1776] 1976b, p. 96).

Keynes also was in favor of spreading wealth and against its concentration in the hands of the capitalist class. He considered scarcity, which is artificially created by the capitalist, to be “one of the chief social justifications of great inequality of wealth.” (Keynes 1936, p.373). Therefore, he sought to eliminate “the cumulative oppressive power of the capitalist to exploit the scarcity-value of capital” because, he argued, “interest today rewards no genuine sacrifice, any more than does the rent of land. The owner of capital can obtain interest because capital is scare just as the owner of land can obtain rent because land is scarce. But whilst there may be intrinsic reasons for the scarcity of land, there are no intrinsic reasons for the scarcity of capital” (1936, p. 376).

The artificial scarcity preoccupied Marx as well, who argued that “[i]t is quite simply the private ownership of land, mines, water, etc. by certain people, which enables them to snatch, intercept and seize the excess surplus-value over and above profit … contained in the commodities of these particular spheres of production …” ([1867–1910] 1968, p. 37) In other spheres of production such as manufacturing, Marx rose against the exploitation of the working class and called for a community based on social justice.

Whereas Smith and early thinkers defined wealth either as production (of goods and services) or as consumption, Marx considered it as the creation of value and distinguished between use value (goods and services pro-
duced for own needs) and exchange value (goods and services produced for sale). Marx wrote:

[a] commodity, such as iron, corn, or a diamond, is therefore ... a use value, something useful. This property of a commodity is independent of the amount of labor required to appropriate its useful qualities. ... Use values become a reality only by use or consumption: they also constitute the substance of all wealth, whatever may be the social form of that wealth. In the form of society we are about to consider, they are, in addition, the material depositories of exchange value. ([1867–1894] 1992, p. 44)

Exchange value, in contrast, exists only when the product is sold. As Marx put it, “a thing can be useful, and the product of human labor, without being a commodity. Whoever directly satisfies his wants with the produce of his own labor, creates, indeed, use values, but not commodities. In order to produce the latter, he must not only produce use values, but use values for others, social use values” ([1867–1894] 1992, p. 48).

If some authors have argued that all members of society should enjoy the benefits of increased wealth, others wanted to exclude the lower classes. In ancient times, the opposition to increased consumption was part of the general criticism of luxury, the desire to get rich, and selfishness. In modern times, the justification has been that consumption by lower classes takes away resources from investment—the key to accumulation. However, one must remember that consumption is what sets apart the different members of society. After all, as the popular adage says, “you are what you eat (consume),” that is, consumption sets your social status. Therefore, we should understand that “[t]he authors hostile to increased consumption ... nearly always conceal (or reveal) a social motive: they are opposed to the rise of the lower classes and fear that their subordination may come to an end. They appear to be concerned about the destiny of the world, but are often concerned merely about the loss of their own privileges” (Perrotta 2003, p. 179).

Thorstein Veblen (1899) saw in the exclusion of the lower classes a means of guaranteeing the power and maintaining the social status of what he called the “leisure class,” for it is through this power relationship that wealth is truly valorized. Preventing the poor from having access to increased consumption is important in the process of valorizing wealth. The logical step therefore is to prevent them from having access to increased wealth, that is, to keep wealth scarce and concentrated in the hands of the leisure class. This is done through what Veblen (1899) called “conspicuous consumption” and “industrial sabotage.” Technology speeds up the production process and increases the total amount of goods and services, thus contributing to eliminate scarcity by gradually shifting luxury consumer goods from being exclusively consumed by the leisure class to being widely available to the lower classes. As pointed out by Charles Clarke,

this tendency must be kept in check, and it is done so by the process Veblen labeled industrial sabotage. Industrial concentration and monopoly are necessary in order to keep profits high.... Thus at the micro level industrial concentration generates scarcity, while at the macro-economic level this is done by keeping the value of money higher than it need be, i.e., keeping interest rates too high. (2002, p. 419)

INTERNATIONALIZATION OF WEALTH AND POVERTY

Advocates of globalization, including the World Trade Organization (WTO), have been arguing that inequality will fall as economies become more integrated and flows of capital and commodities more liberalized. The conclusions of the globalization-equality thesis are based on the neoclassical economic theory according to which free trade (one aspect of globalization) will bring about convergence in commodity prices, whereas factor mobility (another aspect of globalization) will equalize factor incomes by raising the income of the abundant factor and lowering that of the scarce factor. In the context of trade between developed and developing countries, one should expect that incomes of the working poor (the abundant factor) will rise and that returns to capital or even the incomes of highly skilled workers (the scarce factor) will fall. Globalization, therefore, will reduce inequality.

However, this is in sharp contrast with what is observed on the ground. At the national level, available evidence indicates that inequality between the rich and the poor—whether measured by income or by wealth—has been rising in most cases. The United Nations Development Program (UNDP) found that “a study of 77 countries with 82% of the world’s people shows that between 1950s and 1990s inequality rose in 45 of the countries and fell in 16.... In the remaining 16 countries either no clear trend emerged or income inequality initially declined, then levelled off” (2001, p. 17). At the international level, according to the UNDP, the average GDP per capita from various regions as a ratio to that of high-income OECD countries declined between 1960 and 1998, and “in sub-Saharan Africa the situation has worsened dramatically: Per capita income, around 1/9 of that in high-income OECD countries in 1960, deteriorated to around 1/18 by 1998” (UNDP 2001, p. 16). The UNDP summarized its results on world inequality by stating that the ratio of the income of the world’s richest 10
percent to that of the poorest 10 percent has increased from 51:1 to 127:1 between 1970 and 1997.

A study by the World Institute for Development Economics and Research reported that

[s]he figures for wealth shares show that the top 10 percent of adults own 85 percent of global household wealth, … [The corresponding figure for the top 1 percent of adults is 40 percent of global wealth]. This compares with the bottom half of the distribution which collectively owns barely 1 percent of global wealth. Thus the top 1 percent own almost forty times as much as the bottom 50 percent. The contrast with the bottom decile of wealth holders is even starker. The average member of the top decile has nearly 3,000 times the mean wealth of the bottom decile, and the average member of the top percentile is more than 13,000 times richer. (Davies et al. 2006, p. 26)

The unequal distribution of wealth between nations via trade flows was the main argument of the dependency theory in the 1950s. Raul Prebisch (1950) and others have documented this inequality as a transfer of wealth from developing to developed countries in the form of declining terms of trade. Others have argued that underdevelopment (and therefore poverty) is a by-product of the development of Europe and other industrial countries (Darity 1992; Rodney 1972). James Galbraith (2002), on the other hand, showed that the rise in inequality that began in the early 1980s coincided with a sharp increase in real interest rates, an event that had dramatic effects on poor countries, which were forced to adopt austere policies that resulted in more poverty.

Wealth and poverty are not mutually exclusive. They coexist in a dialectical manner; they are both the result of one thing: the unequal distribution of value created in all the stages of production. The mechanisms underlying this unequal distribution have to do with the power relationships leading to the appropriation of profits made from the production and sale of commodities, whether at the national or the global level. The market mechanism cannot bring about social justice. To achieve some form of democratic wealth, redistribution through public intervention is necessary.

**WEAPONRY, NUCLEAR**

The advent of the nuclear weapons age began on July 16, 1945, when the United States tested its first nuclear device in New Mexico at the Alamogordo Bombing Range, now
known as the White Sands Missile Range. The successful nuclear explosion, named Trinity, was the end result of the Manhattan Project, a three-year, $1.9 billion ($26.9 billion in 2005 dollars) effort that brought hundreds of the world’s top scientists together to develop a weapon to be used in the United States’ war efforts against Japan and Germany. Nuclear weapons have been used in warfare on two occasions: on Hiroshima, Japan, on August 6, 1945, and on Nagasaki, Japan, on August 9, 1945. Both bombs were dropped by the United States. As of 2006, eight nations were known to possess nuclear weapons: the United States, Russia, the United Kingdom, France, China, Israel, India, and Pakistan. It is possible that North Korea also possesses a nuclear weapon. In 2003 North Korea claimed to have had successfully developed nuclear weapons. While North Korea has not tested a device, most intelligence estimates believe it is likely that it has nuclear capabilities. South Africa once possessed nuclear weapons but dismantled them in 1993 (see Circinone, Wolfsthal, and Rajkumar 2005).

Nuclear weapons require fissionable materials. When a fissionable atom absorbs a neutron, it will split and release additional neutrons. In a nuclear chain reaction, these neutrons are absorbed into other fissionable atoms that subsequently split and release additional neutrons into other atoms. Nuclear explosions are the result of the rapid release of energy that comes from an uncontrolled nuclear chain reaction.

The two fissionable elements used in nuclear weapons are uranium and plutonium. Uranium is found in nature, but the specific fissionable isotope, uranium-235, constitutes only 0.7 percent of all natural uranium. A nuclear weapon, however, requires uranium-235 to make up over 90 percent of the sample. In order to achieve such a high concentration, the uranium must go through an enrichment process that separates uranium-235 from the more common uranium-238 isotope. This has most commonly been achieved with centrifuges, but other methods, such as gaseous diffusion and electromagnetic isotope separation, have also been successful. Plutonium is not found in nature but is a product of the highly radioactive waste from a controlled chain reaction of uranium, usually performed in a nuclear reactor. To extract plutonium from this waste, a sophisticated chemical process is used. For a country seeking to establish a nuclear weapons program, these large-scale industrial and technical processes can be prohibitive.

Critical mass is the smallest amount of fissionable material that is needed to maintain a nuclear chain reaction. How much uranium or plutonium is needed to reach critical mass depends on various elements of weapon design, such as the shape of the fissile core (gun-type or sphere) or the effective use of reflectors to capture errant neutrons. Most estimates are that between 12 to 60 kilograms of weapons-grade uranium and 4 to 10 kilograms of plutonium are needed. In addition, the efficiency and yield of a weapon can be increased by adding a fusion fuel “booster,” such as lithium-6, as found in thermonuclear weapons.

THE EFFECTS OF A NUCLEAR EXPLOSION

The effects of a nuclear explosion are devastating. The majority of damage is caused by three main elements: blast effects, thermal heat, and ionizing radiation. For example, the bomb that was dropped on Hiroshima, a uranium-type device known as Little Boy, had a yield of 12.5 kilotons of TNT. Of the 76,000 buildings in Hiroshima, 48,000 were completely destroyed and another 22,000 were damaged. According to one study of the Hiroshima bombing, the temperature at the site of the explosion reached 5,400 degrees Fahrenheit and “primary atomic bomb thermal injury was found in those exposed within [2 miles] of the hypocenter” (quoted in Rhodes 1986, p. 714). The heat was so intense that people within a half mile of the fireball were reduced to bundles of smoking char. The number of deaths in Hiroshima due to the bomb is estimated to be 140,000, with an additional 60,000 dying from radiation effects over the next five years.

Since these early devices, the yield of nuclear weapons has grown considerably. Although never deployed, on October 30, 1961, the largest nuclear bomb ever tested was the Soviet Union’s “Tsar Bomba,” which had a maximum yield of 100 megatons. More commonly, modern nuclear weapons have yields ranging between one and 5.5 megatons.

For a one-megaton device, the damage would be even more widespread than at Hiroshima and Nagasaki. According to Ansley J. Coale (1985), the shockwaves from a one-megaton blast would destroy modern multistory buildings within 2.9 miles and unreinforced brick and wood buildings within 4.2 miles of impact. Damage to brick and wood buildings would be substantial up to 8.5 miles from the blast. Heat would cause third-degree burns to exposed skin and set fire to clothing within 4.2 miles. The gamma rays produced from such a blast would be almost immediately lethal to any exposed person within 2.5 miles. People exposed at a slightly greater distance (2.7 miles) would have about a 50 percent mortality rate within a month of the explosion. Finally, a nuclear explosion that makes contact with the ground (as opposed to an airblast) would create tremendous amounts of radioactive fallout that could spread over an area as far as 1,000 square miles downwind from the explosion. Estimates of what percentage would be killed in a one-megaton blast on an urban population vary from 11 percent to 25 percent of
the total population, with an additional 16 to 25 percent injured. Of course, in a nuclear exchange between advanced nuclear weapons states, multiple bombs would likely be assigned to single targets, resulting in even higher levels of devastation.

DELIVERY METHODS
The three main methods of delivery involve ballistic missiles, aircraft, and submarines. Delivery methods are tied to larger strategic and tactical issues related to nuclear deterrence. Nuclear states, such as the United States and the Soviet Union during the cold war, are concerned that a first-strike nuclear attack from another country could be so damaging that it would successfully eliminate any possibility for retaliation. As a result, states design their nuclear forces in such a way that a sufficient number of weapons would remain to respond with a devastating second strike. Many argue that the sole purpose of any nuclear weapon is to deter other states from ever using one. Some also fear that a terrorist organization could gain possession of a nuclear weapon and smuggle it into a major urban center.

Intercontinental ballistic missiles (ICBMs) are launched from reinforced below-ground silos and have ranges of more than 8,000 miles. Often, ICBMs are equipped with multiple warheads—multiple, independently targeted reentry vehicles (MIRV)—capable of hitting multiple targets. Shorter-range ballistic missiles, which could more easily be used in tactical or battlefield scenarios, have largely been eliminated from the arsenals of major nuclear states.

The appeal of aircraft and submarines is their mobility, as well as an enemy’s consequent difficulty in targeting them. Heavy-duty bombers, primarily equipped with up to twenty short-range attack missiles capable of hitting multiple targets, have the ability to penetrate enemy territory and withstand a great deal of abuse. Submarines carrying strategic nuclear missiles can remain below the surface for long periods and can launch missiles capable of hitting specific targets over distances of hundreds of miles. The possession of a nuclear-equipped submarine fleet gives a country a very credible second-strike deterrent.

Since the end of the cold war, both the United States and the former Soviet Union have worked to decrease their nuclear arsenals. However, many fear that tensions between other nuclear states, such as India and Pakistan, and the ongoing threat of further proliferation could result in the future use of nuclear weapons.

WEAPONS INDUSTRY
The fusion of militarism and industrialism was made possible by the Industrial Revolution. In the early industrializing nations of Europe and North America, military leaders harnessed new sources of energy to facilitate transportation (e.g., steam-powered trains and ships) and new means of communication (e.g., the telegraph). This did not require a distinctly militarized industrial sector, only the ability to commandeer commercial goods to feed, clothe, and transport significantly larger military forces. Industrialism also gave rise to the invention of uniquely military end-items and the emergence of large industrial concerns, including defense firms and state-owned armories and shipyards, to produce them. In the twentieth century, this refinement of military goods would give rise to defense firms and the military-industrial complexes (van Creveld 1989).

The fusion of industrialism and militarism facilitated colonialism and conquest. European empires expanded dramatically in the latter half of the nineteenth century, and settler nations such as the United States, Australia, and South Africa completed the conquest of entire continents. Even as they conquered and displaced indigenous peoples, nations such as the United States did not become “warrior” societies. Rather, based on technological advantages afforded by industrialism, European powers and settler nations enjoyed distinct military advantages, often against much larger military forces. To compete on the international stage, military and political leaders in Germany, Japan, and Russia induced industrial develop-
ment in the late nineteenth and early twentieth centuries. These top-down industrialization programs, driven by military priorities, were among the least democratic totalitarian regimes of the twentieth century.

During World Wars I (1914–1918) and II (1939–1945), the industrial capacity of leading economic powers was harnessed to perpetrate an unprecedented slaughter of soldiers and civilians. This industrialization of warfare transformed the battlefield and military organization. Equally important was the social transformation. The mass industrial wars of the twentieth century demanded total mobilization of the armed forces and the economy. In the United States, the iconic Rosie the Riveter called attention to the large number of women contributing to the war effort during World War II, many of whom had not previously worked outside the home. A similar trend unfolded among the industrialized nations fighting industrialized wars. Although the World War II mobilization temporarily redefined the roles of men and women in factories and offices, gender segregation persisted during the war and was reasserted at the war's end (on the U.S. case, see Milkman 1987). These mass industrial wars also transformed the risks and casualties among civilians. Improved record keeping and social control allowed states to identify, transport, incarcerate, and, in some cases, slaughter millions of civilians (the Holocaust being a spectacular example). For these wars, industrial targets in densely populated areas became prominent targets. World War II was especially lethal (Kolko 1994): Large portions of London and several Soviet cities were decimated by German attacks; Dresden and Tokyo were consumed in firestorms and Berlin reduced to rubble; and two Japanese cities (Hiroshima and Nagasaki) were destroyed by atomic bombs.

THE WEAPONS INDUSTRY IN THE COLD WAR ERA

In the course of the cold war (1948–1989), the United States and the Soviet Union built and maintained large weapons industries. The sustained fusion of industrialism and militarism in the postwar United States prompted President Eisenhower to warn the nation and the world about the dangers of the military-industrial complex (Eisenhower 1961). As Eisenhower had warned, the weapons industry distorted technological development and diverted scarce human and physical resources.

During the cold war, a “wall of separation” grew between the defense and civilian sectors of the economy (Markusen and Yudken 1992). Defense-oriented firms and diversified corporations that garnered defense contracts were among the fastest growing and most profitable firms. For the Soviet Union, overinvestment in the military was exacerbated by the war in Afghanistan and costly military and diplomatic commitments around the globe. These chronic fiscal strains contributed to the collapse of the Soviet Union—and with this collapse a dramatic reduction in the size and the scope of the military-industrial complex in successor states. In the twenty-first century, the U.S. arsenal is increasingly reliant on state-of-the-art science and technology. In addition to nuclear weapons, chemical and biological weapons are also produced through sophisticated scientific processes. Even “conventional” forces are being transformed by new sensing, computing, and communication devices being assembled to create an electronic battlefield. Space may become militarized as well. If satellites capable of destroying moving missiles or stationary targets are deployed, highly automated weapons far removed from earth would be at the center of the war and would pose the greatest threat to human life.

CONTEMPORARY DYNAMICS AND THREATS POSED BY THE WEAPONS INDUSTRY

The collapse of the Soviet Union and the end of the cold war raised hopes that the military-industrial complex would be dismantled. In the early 1990s, global military expenditures and arms sales fell as expected. But a resurgence in military spending began in the late 1990s, with the nations of the Middle East figuring prominently. The United States has also increased defense spending since the mid-1990s, to $475 billion in 2005 ($30 billion higher than in 1988). In 2005, the United States accounted for 48 percent of all military spending in the world, an unprecedented level of concentration (Stockholm International Peace Research Institute 2006a).

The resurgence of the military-industrial complex goes beyond the spike in arms production and sales. The changing organizational structure of the military-industrial complex is an equally important—perhaps more important—aspect of this resurgence. When defense spending declined in the 1990s, leading defense firms did not “beat swords into ploughshares.” They redoubled efforts in the shrinking defense market. A round of mergers, acquisitions, and reorganizations occurred: The number of firms declined because of these mergers, and the surviving firms were much larger (see Markusen and Costigan 1999). Whereas the top five firms accounted for 22 percent of the world’s arms sales in 1990, their share doubled (44%) by 2003. With the top five firms accounting for most of the increase, the top twenty firms commanded 57 percent in 1990, and their share of arm sales jumped to 74 percent by 2003 (Stockholm International Peace Research Institute 2006b). Not only are arms sales concentrated in fewer firms, but these firms are concentrated in the United States and a handful of nations.
The increased privatization of national security is also a cause for concern. Private firms have provided construction, logistics support, and so forth to military organizations for centuries. But the growth in the size and range of activities has been notable. The concentration of arms sales in a handful of enormous transnational corporations also concentrates scientific and technical expertise. Governments are growing reliant on corporations (often distant corporations) to plan and coordinate essential national security functions. In addition, corporate mercenaries have played a direct role in toppling governments and in the prisoner abuse committed by the United States during the wars in Afghanistan and Iraq (Isenberg 2004). These mercenaries and the corporations employing them rarely face criminal charges. They not only operate with impunity but also shield the government employing them from democratic scrutiny. In a world in which five firms control more than 40 percent of all arms sales and the top twenty firms account for nearly 75 percent, many governments have lost a measure of control over defense policies. The increased reliance on mercenaries further reduces democratic control and oversight.

Citizens forced to make sacrifices, serve in mass armies, and experience directly the horror of war often question the necessity of fighting. But citizens insulated from the horrors of war often cheer on technological marvels that kill thousands of people and destroy distant cities. Citizens of powerful nations often fail to empathize with the suffering caused by the highly scientific and distant slaughter perpetrated in their name. This callousness is reinforced by the role of major arms-producing corporations. These corporations sell military goods and defense planning to governments around the globe; they also supply mercenaries to fight on the battlefield and interrogate prisoners. By ceding so much control to the insulated corporations of the weapons industry, governments are more distant from their own people and contribute to removing military policies from public scrutiny and democratic oversight. At the dawn of the twenty-first century, our challenge is to restore democratic oversight in a realm dominated by enormous corporations and government bureaucracies.

WEAPONS OF MASS DESTRUCTION

Weapons of mass destruction (WMD) have been used throughout history. While there are definitional ambiguities, all conceptions of WMD imply societally unacceptable levels or forms of destruction. Despite international efforts to curb their spread, concerns over WMD use have increased since the 1990s.

DEFINITIONS AND HISTORIC USES OF THE TERM

The term weapons of mass destruction was first used in a London Times article (December 28, 1937) in reference to the German aerial bombardment of Guernica, Spain, during the Spanish Civil War (1936–1939): “Who can think without horror of what another widespread war would mean, waged as it would be with all the new weapons of mass destruction?” (p. 9). While the Luftwaffe (the German air force) used only “conventional” weapons in the attack, subsequent definitions have emphasized weapons whose materials and effects violate a societal boundary of what is considered “acceptable” in wartime.
The United Nations Security Council Commission for Conventional Armaments (August 12, 1948) defined WMD as “atomic explosive weapons, radioactive material weapons, lethal chemical and biological weapons, and any weapons developed in the future which have characteristics comparable in destructive effect to those of the atomic bomb or other weapons mentioned above.” Since the Iraq War beginning in 2003, the United States has used the term to refer to chemical, biological, nuclear, and, increasingly, radiological (CBNR) weapons. This remains the most common use of the term, although sometimes it is defined more broadly to include any weapons, including conventional weapons, capable of inflicting mass casualties.

**WEAPONS OF MASS DESTRUCTION AND WARFARE**

Chemical weapons include such agents as mustard, sarin, and VX nerve gases, as well as chlorine, hydrogen cyanide, and carbon monoxide. Most chemical weapons are designed to attack the nervous system. They were first used in modern times during World War I (1914–1918) when the French used tear gas during the first month of the war, and during the Second Battle of Ypres (1915) when Germany used chlorine gas in its attack against French and Algerian troops. By the end of the war, more than one million casualties and ninety thousand deaths were attributed to chemical warfare use by all sides. During World War II (1939–1945) the Nazis used hydrogen cyanide and carbon monoxide in the extermination camps, killing millions. More recent chemical attacks include the U.S. use of Agent Orange during the Vietnam War (1957–1975); Iraqi president Saddam Hussein’s use both of sarin gas against Iran during the Iran-Iraq War (1980–1988) and of multiple chemical agents against the Iraqi town of Halabja in 1988, killing up to five thousand Kurds; and Aum Shinrikyo’s sarin gas attacks in Matsumoto (1994) and on the Tokyo subway (1995) in Japan.

Biological weapons are weapons of germ warfare; they include a large number of living agents such as anthrax, botulinum toxin, plague, ricin, smallpox, and typhus. A subclass of biological weapons that could be directed specifically at agriculture includes mad cow disease and swine fever. Although used throughout history, biological weapons have seen limited use in attacks in modern times due to difficulties in creating effective dispersal mechanisms. Exceptions include Japan’s use of biological agents during the Sino-Japanese War (1937–1945) and World War II, including a 1943 attack on Changde, China, that involved an attempt to spread bubonic plague. In 1984 members of the Rajneeshee cult infected a salad bar with salmonella in The Dalles, Oregon, sickening nine hundred, and anthrax was disseminated through the U.S. postal system in 2001, killing five.

Nuclear weapons produce their destructive effects through nuclear fission from chain reactions involving uranium or plutonium or from nuclear fusion (the so-called hydrogen bomb). Considered the most destructive of all WMD, nuclear weapons have been used on two occasions, both at the end of World War II. The bombing of Hiroshima, Japan, on August 6, 1945, killed some 80,000 civilians immediately and another 60,000 from radiation by the end of the year. The attack on Nagasaki three days later ultimately killed 100,000.

Radiological weapons, unlike nuclear weapons, have no blast effect. They derive their destructive power from radiation alone and typically depend on an explosive device to disperse the radiation, although radioactive material could also be sprayed from crop duster planes. Radiological weapons have never been used, but Iraq is believed to have tested them in 1987 for possible use against Iran. The plan was abandoned after it was found that the radioactivity dissipated within a week of the weapon’s manufacture.

**WMD CONTROL**

Due largely to their ability to indiscriminately kill and inflict harm on civilian populations even when the intended target is military, WMD, unlike conventional weapons, have traditionally encountered societal opprobrium. This has led to a number of international agreements to limit their development and use.

The Nuclear Non-Proliferation Treaty (1970) seeks to prevent the spread of nuclear weapons and weapons technology beyond the states already known to possess them. A total of 187 parties have joined the treaty. At least nine countries are known or suspected to possess nuclear weapons as of 2006 (the United States, Russia, Great Britain, France, China, India, Pakistan, Israel, and North Korea). The Comprehensive Nuclear-Test-Ban Treaty seeks to deter development of nuclear weapons by banning all nuclear explosions. The treaty was opened for signature in 1996. As of 2006, the treaty had 176 members but would not come into force until all forty-four nations conducting nuclear research or possessing nuclear power reactors signed and ratified the treaty; eleven ratifications were still necessary in 2006.

The 1925 Geneva Protocol bans the use of biological weapons, and the 1975 Biological and Toxin Weapons Convention bans their “development, production, stock-piling, acquisition, or retention” except for “prophylactic, protective or other peaceful” purposes. The convention has been signed by 162 countries. The United States, Russia, North Korea, and Syria are known or believed to possess biological weapons.

The Chemical Weapons Convention (1997) prohibits the “development, production, acquisition, stock-
piling, transfer, and use” of chemical weapons and requires all signatories to destroy their chemical weapons and chemical-weapons production facilities. The convention was signed by 140 nations; some seventeen nations are known or believed to maintain chemical weapons stockpiles.

Despite efforts to curb WMD proliferation, real concerns remain. One major concern involves their acquisition by rogue states or terrorist organizations. As of 2006, North Korea’s and Iran’s nuclear programs were deemed threatening, and the terrorist organization Al-Qaeda was believed to be seeking some level of WMD capability.

WEAVER, ROBERT C.

1907–1997

Robert Clifton Weaver’s career as economist and presidential advisor spanned the New Deal to the War on Poverty. He produced two major treatises on the economic status of African Americans, Negro Labor (1946) and The Negro Ghetto (1948), and an influential textbook in urban planning and policy, The Urban Complex (1964). Weaver was the first U.S. Secretary of Housing and Urban Development (HUD) and the first African American to hold a cabinet-level position.

Born in Washington, D.C., on December 29, 1907, Weaver earned his doctorate in economics in 1934 from Harvard University. From 1933 through 1944, he held a sequence of advisory positions in the administration of President Franklin D. Roosevelt, including Advisor on Negro Affairs to Secretary of the Interior Harold Ickes (1934–1938) and chief, Negro Manpower Service, War Manpower Commission (1942–1944). From 1961 to 1966, under Presidents John F. Kennedy and Lyndon B. Johnson, he was Administrator of the Housing and Home Finance Administration. President Johnson appointed Weaver the first secretary of HUD in 1966, a post he held until 1968.

Although most of his career was spent in government, Weaver was a consistent critic of government’s failure to end—and occasional duplicity in—the subjugation and segregation of the black population. In Negro Labor, Weaver detailed the participation of government agencies and trade unions in the exclusion of black workers from defense industry jobs. In The Negro Ghetto, Weaver explained how the Federal Housing Authority’s (FHAs) lending practices reinforced local efforts to exclude African Americans from moving into white communities. Weaver argued that segregation would result in deteriorating housing quality and, eventually, to anger, the degradation of social relationships, and increased violence. In essence, he predicted the urban uprisings of the 1960s in 1948.

Walter B. Hill, in “Finding Place for the Negro: Robert C. Weaver and the Groundwork for the Civil Rights Movement” (2005), and Charles and Dona Hamilton, in “Social Policies, Civil Rights and Poverty” (1986), credit Weaver with the creation of a forerunner of modern affirmative action—the minimum percentage clause. This clause, which was inserted into Public Works Administration contracts for low-cost housing, prohibited discrimination on the basis of race or religion and identified, as prima facie evidence of discrimination, a contractor’s failure to hire a minimum percentage of black workers, based on the number of skilled black craftsmen in the locality.

Weaver outlined his vision of how to revitalize these urban centers in The Urban Complex and in Dilemmas of Urban America (1965). Weaver sought to revitalize urban centers through comprehensive, regional planning. Despite the black community’s perception that urban renewal meant “Negro removal,” Weaver remained an advocate of the use of eminent domain, government subsidies, and tax incentives to replace deteriorating, low-cost housing in urban centers. Weaver believed urban renewal projects created the opportunity to replace segregated ghettos with integrated communities. Later, in a 1985 article, “The First Twenty Years of HUD,” Weaver acknowledged the difficulty of realizing this vision.
Following his tenure at HUD, Weaver served as president of Baruch College, City University of New York, and as a Distinguished Professor of Urban Affairs at Hunter College. He died in July 17, 1997, at the age of eighty-nine. In 1999, Congress renamed the HUD headquarters in his honor.

WEBER, MAX

1864–1920

Max Weber helped establish sociology as a social scientific discipline at the beginning of the twentieth century. In Economy and Society: An Outline of Interpretive Sociology (1920) he analyzed modern bureaucracies, the structure of stratification, origins of the city in the West, types of political domination, the genesis of modern legal systems, the importance of religion for social life, and other topics. Perhaps no sociologist, before or since, has displayed his intellectual range and sophistication.

EARLY YEARS

Weber was born on April 21, 1864, in Erfurt, Germany. A gifted child, Weber became politically astute at a young age. His father, a lawyer and politician, entertained prominent people in his salon and the young Weber participated in their discussions.

Weber’s parents were mismatched. His father, a hedonist who enjoyed bourgeois living, ruled the household absolutely. His mother, while loving and affectionate, adhered to strict Calvinist standards of hard work, ascetic behavior, and personal morality. Weber’s wife, Marianne, later reported that he believed he needed to choose between his parents. This dilemma became a source of emotional agony throughout his life. Indeed, his sociological writings may constitute an attempt at working through this inner conflict.

During the 1880s and 1890s, Weber became a successful lawyer and college professor. He had political aspirations. According to Marianne, a distant cousin whom he married in 1893, Weber lived an ascetic life, strictly regulated by the clock. On completing each task he immediately took on a new one. He was chronically overworked, which may have contributed to his eventual collapse.

In 1897 his mother planned a visit with Max and Marianne that his father opposed. Father and son clashed and parted without reconciliation. Shortly thereafter, the old man died. Within weeks, Weber suffered a complete nervous breakdown. At that time, before psychotherapy, the only treatment for such ailments was rest. Weber resigned his teaching position and remained incapacitated for five years. In 1903 Max and Marianne toured America, witnessing its vitality. The trip seemed to rekindle his ability to work.

MAJOR CONTRIBUTIONS

In 1904 Weber posed a simple question: “In what sense are there ‘objectively valid truths’ in those disciplines concerned with social and cultural phenomena?” ([1904] 1949, p. 51). His subsequent writings provide an answer to this query.

Weber’s first goal was to show that objective social scientific research is possible, a controversial position at that time and one that remains divisive. He insisted that sociologists should not infuse research with their personal values, economic interests, or political agendas. As he put it, research should be value free, as unbiased and objective as possible.
This goal carries an important implication: Sociology should not be a politically committed discipline. Rather, Weber distinguished between “what ought to be,” the sphere of values, and “what is,” the sphere of science. Science, Weber said, cannot tell people either how to live or what public policies to adopt. Objective social scientific knowledge can, however, provide them with information necessary to make such decisions ([1904] 1949, p. 54).

In order to achieve this goal, Weber argued that sociologists should apply a “rational method” to their work; that is, they should use clear concepts and systematic observations and then make logical inferences ([1920] 1946a, p. 143; [1904] 1949, p. 105). But this task is difficult. After all, researchers participate in social life, which means they often approach topics with preconceived opinions. Moreover, any specific study only provides a partial picture, which can imply taking sides. The solution to these difficulties is for scholars to critically evaluate and replicate research. Although this practice is imperfect (since human beings are imperfect), it leads to a self-correcting process that produces research findings that are as objective as possible. Given accurate information, Weber argued, sociologists can sometimes suggest strategies for achieving policy goals and possible consequences. At that point, values intrude, since the problem becomes what is to be done. Weber addressed this issue in his essay “Politics as a Vocation,” where he described politics as a process by which competing interest groups seek to affect public policies and the state as monopolizing the use of force in implementing them. The political problem of evaluating and applying scientific findings to practical matters is perennial in modern societies.

Another implication of Weber’s argument for value-free sociology is that the new discipline reflected an ongoing historical process that he called rationalization, in which social life becomes methodically organized based on the use of reason and observation. Weber saw that this process permeates every sphere of modern life: education, work, law, economy, and family. The sciences, of course, including sociology, are the archetypal methodical disciplines. They provide new ways of understanding and controlling our environment, natural and social, opening up dizzying new possibilities. Industrialization, capitalism, democracy, and scientific advance are linked historically, leading to improved lives for most people. For example, they have straight teeth, better diets, and—the ultimate gift—longer lives. All reflect the process of rationalization. In modern societies, then, people look for explanations based on reliable knowledge. They seek solutions to problems rather than accepting fate. This orientation becomes generalized to every sphere: Anyone who uses modern technology learns to approach problems methodically, rather than by relying on magical thinking. But the impact can be disquieting, even frightening, because choices sometimes must be made between competing moral imperatives.

Weber, like many others, feared the impact of rationalization on social life. Knowledge based on reason and observation destroyed magical explanations that had provided meaning for people throughout history. In his essay “Science as a Vocation,” he mused about the “disenchantment of the world” that characterizes modern societies ([1920] 1946a, p. 139). This evocative phrase suggests that humans have passed from an enchanted world of mystery and spirituality into one that is colder, more heartless, perhaps bereft of moral guidance. In a rationalized world, Weber lamented, there are no longer simple answers to the fundamental questions of human existence.

Weber’s second goal was to understand the origin of modern societies. He confronted this issue in his most important book, The Protestant Ethic and the Spirit of Capitalism (1904–1905), and subsequent studies in the sociology of religion. They constitute an exercise in historical hypothesis testing in which Weber constructed a logical experiment using ideal types as conceptual tools.

Ideal types are concepts that identify the essential characteristics of a social phenomenon in the purest form possible. As he put it, they are designed “to be perfect on logical grounds,” which has the “merit of clear understandability and lack of ambiguity” ([1920] 1968, p. 6). Empirical observations, of course, will deviate from the ideal (or pure form). By providing a common point of comparison, however, ideal types set up a logical experiment. They function like a control group in an experiment, and observed variations reflect the impact of causal forces (a stimulus in an experiment) that can be discovered.

In The Protestant Ethic and other studies, Weber explained why capitalism arose in Western Europe and helped to usher in modern life by using ideal types to systematically compare Western Europe in the seventeenth and eighteenth centuries with China and India. What distinguished Europe, he found, was not the level of technology, a free labor force, or other factors. Rather, the West became unique due to the rise of the culture (or spirit) of capitalism as an unintended consequence of the Protestant Reformation.

The Protestant Ethic opens with a then-common finding: “Wherever capitalism … has had a free hand” a relationship existed between Protestantism and economic success ([1904–1905] 1958a, p. 25). Why might this be so? Weber began his answer by describing the “spirit of capitalism” as it existed in the eighteenth century: (1) work is an end in itself; (2) economic success reflects personal virtue; (3) a methodically organized life is inherently proper; and (4) immediate pleasure should be postponed in favor of future satisfaction. Although expressed as ideal types, these cultural values could be observed in the writ-
ings of Benjamin Franklin and others at that time, and can be observed today as well. Weber argued that such values became historically significant as religious asceticism (self-denial) emerged from the monastery and convent into everyday life. The modern world is rationalized (in Weber’s sense) to the degree that ordinary people organize their lives in light of values like these.

Such values originated in the peculiar beliefs of the protesting faith groups. In The Protestant Ethic, Weber examined Puritanism as the ideal type. Puritan life was dominated by unusual ethical norms, which could be observed in pastoral directives: people should work hard, take a methodical approach to everyday life, and use their possessions for purposes that enhance the glory of God. The believers’ underlying motive was purely religious: to ensure they were among the elect going to heaven. The unintended impact, however, was that many of those adhering to such norms became successful, even rich. Moreover, because these religious principles displayed what he called an “elective affinity” with other historical changes occurring at about the same time—the rise of science, democracy, and industrialization—they spread and became secular values. Together, Weber argued, these interrelated changes produced modern rationalized capitalist societies, with their improved lives and potential for disenchantment.

Weber’s third goal was to develop a set of concepts that would be useful for describing and understanding modern societies. This conceptual map comprises the opening sections of Economy and Society.

The “types of social action” illustrate both his theoretical intent and his interpretation of the modern world. According to Weber, people’s actions can be classified in four ways. Instrumentally-rational action occurs when means and ends relate to each other based on knowledge. The model for instrumentally-rational action is scientific knowledge. Because it is based on reason and observation, science avoids self-deception and thus becomes effective in solving problems. Value-rational action is based on values. It always involves demands that people believe compel them to act. Parents educating children; soldiers obeying orders; citizens supporting or opposing abortion; all behave rationally in being faithful to their values. As the examples imply, value-rational action constitutes an end in itself, not a reflection of economic interest. Traditional action is “determined by ingrained habituation” ([1920] 1968, p. 25). In contexts where people are subject to fate, they regulate behavior by custom, often religiously sanctified. Affec
tual action is determined by emotions, and it occurs in all times and places. The parent slapping a child and the basketball player punching an opponent are examples.

Weber argued that traditional action occurs typically in preindustrial societies, where choices are limited (because knowledge is limited) and people have little control over their lives or environment. In such situations, the family usually constitutes both a productive and a consumptive unit, which means that people make economic, legal, and most other decisions in the light of tradition. Tradition (or custom) nearly always precludes the logical evaluation of means and ends based on reason and observation.

Understanding modern societies, Weber said, requires the distinction between instrumentally-rational and value-rational action, although they are interrelated in practice. The pervasiveness of instrumentally-rational action reflects the process of rationalization. People use values, however, to channel behavior. For example, they emphasize increasing knowledge, individual autonomy, protecting life, and equal opportunity, among other fundamental moral guides. In such contexts, bureaucracies become the means of administration. Their common objective is to create and enforce rules efficiently, fairly, flexibly, and competently in order for government to operate in the public interest or companies to produce goods and services. In their pure (or ideal type) form, bureaucracies constitute a model of instrumentally-rational action. Ideally, administrators obtain positions based on qualifications, personal and official affairs are kept separate, decision-rules are based on reason and knowledge, and rules are applied uniformly.

In the real world, of course, human beings comprise bureaucracies, which means they do not meet these standards perfectly. For example, corruption occurs and rules are not always applied uniformly—who one knows often makes a difference. Moreover, bureaucratic procedures (following the rules) sometimes become more important than the goals they are designed to achieve—an irrational result. The ideal type, however, provides a point of comparison, a way of evaluating people’s performance in bureaucratic organizations.

Still, Weber was pessimistic about the future. The ability to obtain “objectively valid truths” about both natural and social phenomena has radically increased human understanding and improved people’s lives. But it also stripped the supernatural of its ability to explain the meaning of life. At the same time, Weber showed in The Protestant Ethic that while the religious roots of the spirit of capitalism have died out, Puritanism bequeathed to modern people “an amazingly good, we may even say a pharisasically good, conscience in the acquisition of money” ([1904–1905] 1958a, p. 176). The Puritan, he wrote, wanted to work hard for the glory of God; we are forced to do so. But for what reason? In a disenchanted world, this question becomes hard to answer. In this context, Weber feared, the culture of capitalism, combined with capitalist social, economic, and political institutions, would place people in a bureaucratic “iron cage” from which there
might be no escape and for which there is no longer a religious justification. This possibility led to Weber’s last, sad lament: “specialists without spirit, sensualists without heart; this nullity imagines that it has attained a level of civilization never before achieved” (p. 183).

COMMENTARY
The problem of objectivity remains one of the most vexing in sociology. On the one hand, some reject the goal, arguing that sociology must be politically engaged. Among the classical theorists, both Karl Marx and Émile Durkheim embraced this position, although in quite different ways. Many early American sociologists also held this view and some continue to do so in the twenty-first century. The idea is that an activist discipline can be a force for good, liberating people from oppression. On the other hand, the logic of Weber’s argument suggests that a discipline committed to political change would produce unreliable knowledge and, hence, become politically irrelevant. Many, perhaps most, sociologists agree that the goal of objectivity should animate the discipline, even though its achievement can be difficult.

The “Protestant Ethic” thesis became controversial immediately and remains so today. A typical criticism is that capitalism has existed in some form throughout history. This is correct, but not Weber’s point. He distinguished between the traditional enterprises of a few “adventurer capitalists,” who sought windfall profit sufficient to last a lifetime, and a modern rationalized capitalist economy, which is based on the mass production of consumer goods in an environment where everyone strives to make money as an ethical duty. A more accurate criticism is that Weber missed the existence of functional equivalents to the protestant ethic in other parts of the world, such as China and Japan. This assessment provides a simple example of how the social sciences can be self-correcting. The Protestant Ethic also became important because its logic suggested some of the limitations of Marx’s analysis. Marx argued that political and economic interests guide action. Weber agreed but added that ideas and values function like railroad switchmen: They determine the tracks along which interests push action. For example, people sometimes vote against their economic interests because of their values. In fact, in today’s rationalized world, people lead methodical lives and use reason buttressed by knowledge to achieve their values.

Weber and Marx constitute opposing poles among the classical sociologists. Both were structuralists, emphasizing the importance of understanding the context in which people make decisions. But while Marx posited the existence of historical laws of development in which feudalism led inevitably to capitalism and the latter to communism, Weber replied that history has no direction. Rather, as it occurs, history is messy and disorderly. Observers see patterns only in retrospect. Capitalism, he pointed out, arose in the West based on a series of unpredictable historical accidents, such as the Protestant Reformation. Both stressed the importance of human decision making, but again in different ways. Marx argued that inequality would increase to unsustainable levels in capitalist societies. In this context, he claimed, alienated people who did not own the means of production would rebel and usher in a new, communal society. Marx was wrong. Writing a half-century later, Weber saw that capitalism combined with industrialization to produce a middle class. He worried instead about the possibility of reason run amok: In a “disenchanted” world, “rationalized” bureaucracies would oppress people, creating conformists without a sense of ethical responsibility.

Although Weber may have been too pessimistic, the historical process of rationalization creates huge dilemmas that are not easily resolved. It is secularizing, thus frustrating a deeply felt human need for what Weber called “theocies,” ways of understanding and coping with suffering and evil. It is individuating, which leads to a paradox: People come to value both individual autonomy and communal bonds. And it is liberating, as many areas previously determined by fate become opportunities for choice—by individuals, the state, or both. For example, one of the benefits of modernity is the gift of long life and an increasing ability to control the circumstances of death. In this context, what ethical criteria should individuals use in making end of life decisions? As interest groups offer their competing solutions, how should policy makers evaluate the political, economic, and ethical considerations surrounding this dilemma? The simple answer provided by tradition—thou shalt not kill—becomes difficult to maintain when individuals’ right to life must be balanced against their freedom and autonomy. Moral imperatives collide. Weber saw this essential feature of modern capitalist societies perhaps more clearly than any other classical sociologist.

Toward the end of his life, Weber seemed to find release from his psychic wounds. Marianne reported that his ability to work became steadier and sleep more regular. He began teaching for the first time in more than twenty years, giving two of his most famous lectures: “Science as a Vocation” and “Politics as a Vocation.” He also reworked his explanation of the origins of capitalism and began composing the conceptual map that frames the substantive portions of Economy and Society. During the summer of 1920 Max Weber developed pneumonia. He died on June 14; he was only fifty-six years old.

Body weight is most commonly measured in kilograms or pounds. Body mass index (BMI) is a frequently used measure and serves as an index of weight-for-height calculated in kg/m². BMI is often used to stratify individuals into categories ranging from underweight to severely obese. One critique of BMI is that it does not distinguish between muscle and fat mass (Kraemer et al. 1990). Anthropomorphic measures (e.g., waist circumference) enhance measurement accuracy by examining distribution of excess weight around the abdominal region. Negative health consequences are associated with a waist circumference > 102 centimeters for men and > 88 centimeters for women (NIH 1998). Total body fat percentage is also used to measure excess weight and can be calculated by skin-fold caliper, hydrostatic weighing, or bioelectrical impedance testing.

Statistics compiled by the Centers for Disease Control and Prevention (CDC) indicate that in 2006 two-thirds of adults in the United States were overweight and 32.2 percent met the criteria for obesity. Moreover, obesity prevalence rates among children and adolescents have tripled since the mid-1980s (Ogden et al. 2003). These trends are alarming because obesity is the second leading cause of preventable death and a risk factor for chronic illness, including type 2 diabetes, hypertension, and coronary heart disease.

Although the causes of obesity are not fully understood, it is viewed as a chronic disease influenced by genetic, environmental, behavioral, and cultural factors. Research suggests that genetic influences account for a significant amount of variability in BMI. Findings from twin studies suggest that up to 70 percent of variation in BMI can be accounted for by genetic factors, while adoption studies have produced more conservative heritability estimates of 20 to 30 percent (Bouchard 2002). However, genetic influences do not account for the dramatic and steady increase in the prevalence of obesity (Brownell 1994). Environmental factors, such as the widespread availability of calorie-dense foods and urban development not conducive to physical activity (e.g., lack of parks and busy intersections), also have contributed significantly to the rise in obesity.
SOCIAL CONSEQUENCES OF WEIGHT

A thin physique continues to be the accepted ideal in Western cultures despite a steady increase in the prevalence of overweight and obesity. Fashion models and popular cultural icons have become increasingly thin since the 1960s (Wolf 1991). Dissatisfaction with body weight has become the norm, especially for women (Rodin et al. 1985). In fact research suggests that 52 percent of men and 66 percent of women in the United States are dissatisfied with their weight (Garner 1997), and some women report dieting even when their weight is at or below normal (Rodin et al. 1985). However, there are racial differences on satisfaction with weight (Gluck and Geliebter 2002). Relative to white females, African American females report less concern about dieting and fatness (Rucker and Cash 1992). In addition, compared to overweight white females, overweight African American females are more satisfied with their bodies and feel more attractive (Stevens et al. 1994). While the overwhelming majority of women desire to lose weight, it is somewhat different for males. Although a substantial percentage (88%) of men who are dissatisfied with their weight desire to lose weight, 22 percent of men who express dissatisfaction with their bodies actually wish to gain weight (Garner 1997). This is most likely due to the muscular ideals that are portrayed for male physiques (Drewnowski and Yee 1987; Frederick et al. 2005).

Weight-related stigmatization is prevalent in Western cultures, and data suggest that there has been an increase in weight bias since the mid-twentieth century (Lattner and Stunkard 2003). Of the many conditions that are stigmatized in Western culture, it has been suggested that the stigma associated with being overweight may be the most debilitating and harmful (Sarlio-Lahteenkorva et al. 1995). Overweight individuals perceive stigmatization from co-workers, strangers, friends, and spouses (Friedman et al. 2005). Obesity also negatively affects employment (Rothblum et al. 1990) and socioeconomic status (Puhl and Brownell 2001). In addition data suggest that weight-based stigmatization negatively impacts the mental health of obese individuals (Friedman et al. 2005) and may contribute to overeating behaviors (Ashmore et al. 2007).

WEIGHT AND MENTAL HEALTH

Studies examining obesity and mental health have yielded mixed results. Earlier studies reported no significant mental health differences between community samples of obese and healthy-weight individuals (Wadden and Stunkard 1985). More recently, data from the National Health and Nutrition Examination Survey revealed a 1.5-fold higher risk for major depression among obese individuals relative to healthy-weight cohorts. Results suggested that severely obese individuals were at greatest risk for depression (Onyike et al. 2003). Several reviews suggest that the risk for major depression is particularly significant among the severely obese and those seeking surgical treatment for weight loss (see Wadden and Sarwer 2006), suggesting that extreme obesity is related to increased depression.

TREATMENT

Management of obesity is a major health-care challenge. There is a range of available treatments, including lifestyle modification, pharmacotherapy, and bariatric surgery. Typically, a step-care approach is taken with the least invasive intervention attempted first. Most treatments produce some initial weight loss; however, behavioral and pharmacological interventions have been largely unsuccessful in the long-term maintenance of weight loss among the severely obese (NIH 1998). Behavioral and pharmacological treatments for obesity typically result in a 5 to 15 percent weight reduction when successful, though patients often have higher weight-loss goals (Foster et al. 1997). According to the National Heart, Lung, and Blood Institute, surgical intervention is an option when BMI > 40 or > 35 in the presence of comorbid conditions (e.g., hypertension, diabetes). Follow-up studies of weight-loss surgery patients demonstrate 49 percent maintenance of excess weight loss over a fourteen-year period and resolution of many medical comorbidities (Pories 1995).

**Welfare**

---

**WELFARE**

Welfare is typically a term that denotes varying kinds of social spending allocated by governments following industrialization in nation-states. Prior to industrialization, most governments left assistance for the underprivileged to landlords in feudal systems, private organizations, and (primarily) the Catholic Church. Such “poor relief” became known as “welfare” following government intervention in such provisions.

The pairing of government and poor relief can be traced in part to responses to natural disasters—such as earthquakes, fires, and floods—that led monarchical governments to feed people and rebuild homes in order to preserve order. This definition of welfare—providing assistance to those who are otherwise unable to feed, house, or clothe themselves—remains the primary guide to most countries and scholars who study and implement welfare programs. Thus “welfare” is commonly considered to include redistributive policies and programs that enable the disadvantaged to reach some minimal level of existence within a nation-state.

Many nation-states now provide varying levels of housing assistance, income supplementation, in-kind goods and service provision, and public education as part of the welfare state. The programs and policies to provide these aspects of a minimal human existence can vary. For example, income supplementation can consist of cash payments, tax credits, or child-care subsidies. Similarly, in-kind goods and services can include vouchers for food, free or subsidized medical care, and free job training or referral services. Each nation (and in federal systems such as the United States, each state) makes decisions regarding: (1) the financial commitment to make to these programs; (2) the kinds of programs to provide to its poor; and (3) who is eligible to receive aid under the programs.

The comparative welfare-state literature and the public-policy literature have determined that several factors interact in producing fiscal outcomes and programmatic decisions made at the national level. Most of this work has focused on comparing European nations with other developed democracies such as Canada, Australia, and the United States. Other work has also compared Western
nations such as these with Asian democracies such as Japan and socialist states such as the former Soviet Union, Cuba, and China. The primary findings from these examinations focus on three types of variables to explain and predict both the level of funding and the kinds of programs that are developed: (1) the system of political institutions in place; (2) the attitudes among the citizenry and policymaking bodies toward the poor; and (3) the level of racial/ethnic heterogeneity within the polity.

The political system comparisons proceed at the national level and focus first upon whether federal systems or unitary systems tend to provide greater redistribution to the poor. In particular, the federal system of the United States has been frequently cited as one reason why the United States lags so far behind most other similarly situated nations in terms of social welfare provision. The United States stands alone among OECD (Organization for Economic Cooperation and Development) nations, for example, in its dependence on private health care as 35 percent of total health expenditures. Far smaller and less-developed nations in Europe and in Asia provide universal or near-universal public health coverage. In addition to these systemic differences, comparative welfare-state experts focus on the types of institutional arrangements that may produce different kinds of welfare program provision. For example, states with proportional representation systems have over the course of history had greater influence from left-of-center ideological parties working in coalition governments; winner-take-all electoral systems require far less coalition politics and therefore depress the influence of parties that would seek greater redistribution when they lose elections.

Both systems and institutional arrangements are shaped by the parties that enter power and whether they are required to respond to the electorate in their policymaking decisions. In cases where the electorate plays a significant role in determining the allocation of power, political parties reflect to a large degree mass public opinion regarding the views of the poor. In countries where the electorate views the poor as “trapped in poverty,” more generous and comprehensive welfare programs exist. Where the majority of the electorate views the poor as “lazy,” less generous and comprehensive welfare programs exist. Where moves toward less generous and comprehensive programs succeed, the burden continues to fall on private relief organizations (including religious organizations), as it did prior to industrialization. Although there is a direct correlation between public opinion and welfare policy, such a correlation is also shaped by both the institutional arrangements and the degree of racial/ethnic heterogeneity in the country.

In addition to institutional arrangements and mass public opinion, the degree of racial/ethnic heterogeneity plays a unique role in the provision of welfare benefits at the national level. Racial/ethnic animus has been examined at length in more diverse societies as a factor that depresses the likelihood of generous or comprehensive welfare policy. However, a strict breakdown between ethnically diverse countries and homogenous nations does not explain the variation. In fact, it is those countries with both racial/ethnic diversity and a concentration of poverty among the ethnic/racial minorities that leads to an “anti-solidarity” effect: Both the mass electorate and the parties that represent them are less likely to provide welfare benefits to a subset of the population that is perceived to be undeserving.

In the United States, for example, race- and income-based disparities in the provision of health-care coverage have existed since the founding of the American welfare state with the Social Security Act of 1935, which exempted select industrial sectors employing large numbers of African Americans from old-age salary replacement and medical coverage programs. While federal and state legislation has since outlawed the exclusion of citizens on the basis of race from such programs, race- and income-based disparities in program participation persist.

The cross-national analyses of welfare provision generally tend to focus on states that are capable of providing welfare benefits domestically, whether through capitalist or socialist economic systems. Much less attention has been given in such analyses to the role of international or global organizations that attenuate dire situations in countries that are incapable at the national or local level of providing such services. A separate literature contends with the role of international organizations such as the World Health Organization, the International Monetary Fund, and the United Nations in the provision of welfare benefits to developing nations. Future comparative research can and should integrate these literatures to comprehensively determine the relevant weights of the three factors identified above—the system of political institutions, mass public opinion, and racial/ethnic heterogeneity—to examine how the outcomes of welfare policymaking serve to further stabilize and strengthen democracy, or serve to undermine it.

Welfare economics is the study of how a society can best use its scarce endowments—for example, its natural resources, technical know-how, stock of physical and human capital, and so forth—to maximize the well-being of its members. When the principles of welfare economics are used to evaluate a specific policy issue, it is known as welfare analysis. This entry describes the main features of welfare analysis, focusing on its intellectual foundations and practical challenges, as well as controversies surrounding its use.

Two policy examples will help clarify what welfare analysis is. First, psychologists have shown that the academic achievement of underprivileged children is significantly improved by enrollment in prekindergarten programs. These programs are, of course, expensive to run. Will society be better off if prekindergarten is freely and universally provided? Second, as of 2007, high gas prices have caused U.S. policymakers to consider opening the Arctic National Wildlife Refuge in Alaska for energy exploration. Would the benefits to society from the increase in domestic energy sources outweigh the environmental implications of this decision?

Neither of these questions has an obvious answer, although each can invoke varying opinions from different members of society. The task of welfare analysis is to assemble information to aid in determining whether the proposed policy action would on balance be beneficial to society. Economists use two fundamental concepts to aid in this process. The first is consumer sovereignty, which has its roots in the philosophy of individualism. Consumer sovereignty has two related consequences for welfare analysis: it implies that the individual is the best judge of what is good or bad for his or her well-being, and that a proposal can only be judged by examining the sum of its impacts on individuals. The latter gives rise to the second fundamental concept, the compensation criterion, as originally proposed by John Hicks (1939) and Nicholas Kaldor (1939). Almost any policy action will involve winners and losers. The compensation criterion suggests that a policy is desirable if those who gain from the action gain enough in aggregate that they would be able to compensate the losers for their losses. Thus welfare analysis is a matter of measuring changes in individuals’ well-being as they see it as a result of a policy change, and determining whether the sum of the individual gains is greater than the sum of the individual losses.

This view of welfare analysis might more accurately be described as the neoclassical interpretation in that it is intentionally silent on issues of fairness, justice, and other notions of equity. Said another way, neoclassical welfare analysis focuses narrowly on maximizing the size of the well-being pie rather than providing prescriptions on how it should be divided. Implicitly, distributional questions are left to other mechanisms. A wider view of welfare analysis requires specific judgments on what is fair and just and hence is more difficult to implement. Nonetheless there have been efforts by political economists past and present to cast welfare analysis in a wider light. Prominent among these is the work of Amartya Sen, who advocates the use of mild interpersonal comparisons—based, for example, on the ability of people to freely choose their lifestyle—in conjunction with neoclassical criteria. The work of Sen and others notwithstanding, the narrow view of welfare analysis as described above has tended to dominate the operational use of the technique.

The operational challenge of neoclassical welfare analysis is to assess changes in well being from an action. Because a person’s well being cannot be objectively measured, economists use money proxies in their stead. A prime example of this is willingness to pay, which measures how much money a person would pay out of their income to secure (or prevent) an action. This measure is valid and useful even if the payment is not actually made. The magnitude of the payment, if accurately assessed, provides a sense of the relative importance of the action under consideration. Techniques for measuring individuals’ willingness to pay have a long history in economics, beginning with Alfred Marshall (1930) and including seminal works...

The principles of welfare analysis (if not always the techniques) are widely accepted by economists. Nonetheless, they can be controversial among noneconomists. Three of the main points of contention deserve mention in closing. First, some object on ethical grounds to the use of money measures to gauge the value of public policy issues related to, for example, human health and the environment. Second, based as it is on the notion of individualism, welfare analysis does not readily admit notions of collective responsibility. Finally, welfare analysis tends to be silent on the subject of income distribution. Nonetheless, welfare analysis is often the only means available to policymakers of organizing complex and conflicting points of view; as such, it will likely continue to play a role in policy decisions.

WELFARE ECONOMICS

Welfare economics is a normative branch of economic theory that attempts to assess the implications of laws and institutions, including market outcomes, for human well-being. Welfare economics begins with John Stuart Mill’s “canons of taxation,” in which he applies rule-utilitarian ethics to suggest guidelines for taxation that might reduce its bad impacts. Nevertheless, A. C. Pigou’s Economics of Welfare (1920) can be thought of as the founding book of welfare economics. Among the propositions of welfare economics there would be a broad consensus, for example, that (1) in the absence of externalities, competitive equilibria are efficient, and (2) with few exceptions, taxes, monopoly power, and externalities tend to move the economy predictably away from an efficient allocation of resources.

THE UTILITARIANISM OF MILL AND PIGOU

The ideas of Mill and Pigou are utilitarian in the narrow sense that they assume the following:

1. Acts, laws, rules, and institutions should be evaluated on the basis of their consequences rather than on some intrinsic rightness or wrongness; that is, nothing is good unless it does somebody some good.

2. Good and bad subjective states of mind are the consequences that should be considered in the assessment.

3. For a particular individual, the degree to which good states of mind are attained, and bad states avoided, can be expressed by a number (called utility).

4. Moreover, this number can be compared between individuals and cumulated over the population; and so this cumulative number can be made the objective of public policy.

This narrow utilitarianism would imply, among other things, that efficiency depends on the distribution of income as well as the allocation of resources. Many economists found this undesirable, on the grounds that one ought to be able to assess the efficiency of resource allocation apart from the distribution of income, as indeed Mill had suggested. This led them to reject the fourth assumption. For this purpose, Vilfredo Pareto had proposed the criterion that bears his name: An allocation of resources is said to be “Pareto optimal” if no one person can be made better off without making another person worse off. Without interpersonal comparability of utility, however, no discrimination can be made among Pareto optimal allocations as to which is better or worse.

Moreover, to some, the third assumption also seemed implausible. In place of numerical or “cardinal” utility, they held that individual decisions and well-being are based on a system of preferences. The “good states of mind” are the ones that the person prefers (which may not correspond to pleasure and pain), and therefore the vectors of consumption goods and services that produce the states of mind can be placed in an order from better to worse, from that individual’s point of view, but the ordering does not
correspond to any unique numerical measure. As Paul A. Samuelson (1948) observes, however, the preferences could in principle be reconstructed from ("revealed" by) the observed choices of the individuals. The revision of welfare economics without the last two assumptions is known as the "new welfare economics."

INDIFFERENCE CURVES
A preference system can be visualized by a map of "indifference curves." Beginning from a particular vector of consumer goods, such as "one coffee and two doughnuts," the indifference curve corresponding to that vector is the boundary between all of the vectors preferred to "one coffee and two doughnuts" and those to which "one coffee and two doughnuts" is preferred. If one assumes that this boundary is well-defined, it forms a curve with the property that, taking any two vectors along the curve, the individual feels no preference for one over the other. Thus, for example, if "one coffee and two doughnuts" and "two coffees and one doughnut" are on the same curve, then the individual can be said to be indifferent between the two, and accordingly the curve is called an indifference curve. The preference map can also be represented by any one of an infinite array of "utility indices," provided that, comparing two consumption vectors, the higher number is assigned to the one that is preferred. In this case, however, the only valid conclusions of the analysis are those that do not depend on the specific utility index numbers used.

Francis Ysidro Edgeworth addressed the efficiency of allocation of goods in a pure exchange economy using the indifference curve approach (1995). First, assume that the total quantities available of two goods, good \( x \) and good \( y \), are \( X \) and \( Y \) as shown in Figure 1. If the coordinates of a point in the interior of the diagram are \( x_0, y_0 \), then those are the quantities of the two goods allocated to individual \( j \), and the quantities allocated to individual \( k \) are \( X - x_0, Y - y_0 \). Thus, the indifference curves for individual \( j \) are oriented to the \( x, y \) axis and are shown by curves 1, 2, 3, while the indifference curves for individual \( k \) are inverted and are illustrated by curves \( i, ii, iii \). The points of tangency of two indifference curves, shown by the contract curve \( LM \), are all Pareto optimal allocations of the two goods between the two individuals. In general, then, there will be infinitely many Pareto optima. A shift from one Pareto optimum to another trades off one person's preferences against those of the other person.

To visualize this trade-off, one assigns a numerical index \( u_j \) to each indifference curve 1, 2, 3 and a numerical index \( u_k \) to each indifference curve \( i, ii, iii \). One must keep in mind that these arbitrary indices of utility cannot be compared as between the two individuals nor added. Figure 2 shows a diagram with \( u_j \) on the horizontal axis and \( u_k \) on the vertical axis. Any combination of utility indices (indifference curves) on or beneath this curve are attainable when \( X \) and \( Y \) are produced, while none of the combinations beyond the curve are attainable. This is called the constrained utility possibility frontier corresponding to the production of \( X \) and \( Y \).

Suppose one carries out the same exercise for each technically efficient, feasible set of outputs \( X, Y \). One
would then trace the outer limit of all of the constrained utility possibility frontiers obtained in this way. This outer limit is the grand utility possibility frontier or simply the utility possibility frontier. With an appropriate change in the definitions of $u_1, u_2, \ldots, u_m$, one may take Figure 2 as illustrative of the utility possibility frontier. Every point on this frontier has the properties that (1) the two goods produced are allocated between the two persons in a Pareto optimal way; and (2) production is technically efficient—that is, no reallocation of resources can increase the production of one good without reducing the production of the other; and (3) therefore, production and allocation is Pareto optimal over all possible allocations of resources and consumer goods. With appropriate mathematical notation, this conception can be extended to very large numbers of distinct goods and services and a very large population of agents.

SELECTING ALLOCATIONS

Two issues remain in this analysis. First, how does one choose the “best” among the points on the frontier? Second, for many practical problems, one must choose between two allocations, at least one of which is not Pareto optimal. How may one do that?

Taking these questions in reverse order, the new welfare economics answers the second question with a cost–benefit analysis based on the “Kaldor-Hicks compensation test,” named after Nicholas Kaldor (1939) and John R. Hicks (1939). One may illustrate this compensation test with an example of property on the banks of a river. John Doe owns land on the banks of Flowing River, while Richard Roe owns downstream property, including both banks. Roe builds a dam, entirely on his own property. The impoundment of Flowing River floods Doe’s property. In this sequence, Roe is the gainer and Doe the loser in clear senses. But can one say that Roe’s benefits exceed Doe’s costs?

To answer this question, one considers whether Roe could allocate some of his benefits to compensate Doe and still be a gainer on net? This is the Kaldor-Hicks test, and if the answer is yes, then building the dam is a potential Pareto improvement. That is, if the dam is built, there is a distribution of income that would leave everyone in society better off than they were without the dam. But another, equally reasonable, compensation test asks: Could Doe compensate Roe for ceasing and desisting from dam building, so that Roe would be better off than he would be if the dam were built? This is the Scitovszky test—named after Tibor de Scitovszky (1941)—and if the answer is yes, the world without a dam is potentially Pareto superior to the world with the dam. The two tests would be equivalent if benefits and costs were independent of the distribution of wealth, but, as Hicks noted, they are not. If the dam is built, and compensation is not paid, then wealth is redistributed and a new situation created. From the new situation, it might be a potential Pareto improvement to return to the original position. In practice, there is likely to be little difference between the two, because the impacts of the shifting income distribution is likely to be small relative to the impact of a project, and the Kaldor-Hicks test is the one usually used.

THE SOCIAL WELFARE FUNCTION

Is it possible, then, to choose one among the allocations on the utility possibility frontier that is the optimum of optima? For example, some might prefer an allocation with a more equal distribution of income or one in which certain “basic needs” are more thoroughly met, or that satisfy other conditions. Ideally, one might hope to express some consensus of such conditions in a social welfare function that would indicate which allocations are socially preferable to other allocations independently of their technical feasibility. Visualizing this social welfare function as a set of social indifference curves, and superimposing it on the grand utility possibility frontier, results in Figure 3. In this figure, the grand optimum allocation of resources could be identified with point $V$. Further, following Samuelson (1956), the utility index could be made an index of real income. Remember that any numbers that correspond to indifference curves and assign larger numbers to the more highly preferred curves can be used as utility index numbers. In general, an index of real income will have this property. Therefore, suppose the axes meas-
ure the real incomes, $R_j$ and $R_k$, of the two individuals. With this interpretation, the curvature of the social indifference curves could express one's attitudes toward income equality, so that, for example, social indifference curves tightly curved around the 45-degree line would express a strong preference for equal incomes.

This ideal was set back by the Nobel laureate research of Kenneth J. Arrow (1951), in his general (im)possibility theorem. Arrow showed that, if we require some reasonable-seeming conditions on the social welfare function, such as the requirement that it generate transitive preferences, there could be no social welfare function that would satisfy them all. For a system of majority rule, for example, Arrow adapted a paradox attributed to the marquis de Condorcet (1972) to show that (imposing his other conditions) voting outcomes could always be cyclical rather than transitive. But Arrow also extended this to any (nonmajoritarian) social welfare rule, and in the context of his theorem, it is equally impossible to say that a market outcome defines a social welfare optimum.

Arrow's theorem has spawned a large literature of reconsideration. Sometimes the conditions he proposed for a social welfare function can seem less self-evidently appropriate on further consideration. For example, one of the conditions is "nondictatorship," mathematically expressed; but in some simple models of majority rule, the median person is a "dictator" in Arrow's mathematical sense, although not on a conventional understanding of dictatorship. Thus, much of the controversy has centered on the refinement of Arrow's conditions, and there is a large variety of possibility and impossibility theorems. All the same, Arrow's discussion raised enough doubts about the concept of a social welfare function that it has been little used since the mid-twentieth century.

NEW UTILITARIAN APPROACHES

The new welfare economics is utilitarian only in the broader sense in that it accepts assumptions (1) and (2) above. But the narrower utilitarian approach is not dead. Game and decision theorists reformulated utility theory so that an objective numerical measure of utility can be based on observations of risk-averse behavior. In social philosophy, John Rawls (1971) renewed the social-contract theory, arguing that public policy should promote the interests of the least-favored individual. One interpretation of this is that it demands interpersonal comparison of utility and supplies a social welfare function based on the minimax principle. Drawing on the reformulation of utility theory and Rawls's social-contract approach, John C. Harsanyi (1975) argued that social welfare could after all be based on a summation of individual utilities. Like Harsanyi, Amartya Sen (1985) admits interpersonally comparable utilities, at least as a logical possibility, and he has proposed conditions less limiting than Arrow's that allow the possibility of a consistent majoritarian social welfare function. Sen, however, rejects what he describes as the welfarism of both the old and the new welfare economics, by which he means the supposition that the goodness of a social system depends only on the welfare of individuals in those social systems. In addition, Sen would have data on the capacities and perhaps freedoms of individuals reflected in the normative evaluation of economic society.

For many welfare economists, inequality in the income distribution is something to be avoided, but that cannot be completely avoided because of the sacrifice of production that would result. But inequality is not a simple thing in itself. Anthony Atkinson has made important contributions to the measurement of inequality and incorporation of inequality in discussions of policy issues such as taxation and fiscal policy. In 2001, Atkinson addressed "The Strange Disappearance of Welfare Economics." Atkinson does not suggest that welfare judgments are disappearing from economics. Quite the contrary. For Atkinson, “welfare economics” comprises systematic and critical thinking in normative economics, and he notes with regret the de-emphasis of welfare economics from graduate programs and from the current research literature. The result, he suggests, is a proliferation of ill-considered value judgments in economic research, including a good deal of prejudice and confusion. Atkinson illustrates this with examples from recent macroeconomics, a field which perhaps has never been rich in careful thinking on value issues. For Atkinson, then, welfare economics has never been more needed, although this field of study receives far less attention than it did two generations ago. On the whole, nevertheless, welfare economics is a highly developed branch of economic theory that supplies tools for applications in cost–benefit analysis, but that also raises unsettled questions for future research.

WELFARE STATE

The welfare state is a set of government programs aimed at ensuring citizens' welfare in the face of the contingencies of life in modern, individualized, industrialized society. All welfare states provide direct state assistance to the poor in cash (e.g., social assistance) and in kind (e.g., housing and social services), as well as social insurance against the financial consequences of certain biological risks (illness, incapacity to work, childbirth, child-rearing, old age) and occupational risks (unemployment, accident, or injury). Whereas social assistance—in the United States popularly termed welfare—entails redistribution from the non-poor to the poor, social insurance rarely does so and instead can be understood primarily as redistribution across the individual life course, from periods of employment to periods of inability to work. (Prominent exceptions would be the U.S. public pension system, Social Security, and the German social health insurance scheme, both of which are moderately redistributive across classes.) Usually, this latter type of social protection is available only to persons who have been employed and hence contributed to the relevant social insurance scheme.

In most welfare states, substantial efforts are also made to mitigate socioeconomic inequalities in primary income distribution through secondary redistribution, that is, government spending on social programs funded by progressive income taxation together with tax expenditures (tax deductions for social-insurance or charity contributions, as well as negative income taxation for the working poor). Historically, such reductions in socioeconomic inequality have been pursued to achieve four objectives: (1) to reduce the costs of production for employers, especially through unemployment, health, and pension schemes; (2) to maintain social peace, that is, to forestall both radical unionism within the factory, primarily via accident insurance, as well as threats to private property from leftist or rightist political radicalism in society as a whole; (3) to secure equality of economic opportunity, seen as conducive both to social peace and to economic growth; and (4) to enrich the status of citizenship beyond civil and political equality by including a social dimension, as articulated by T. H. Marshall in 1950. Countries pursuing this goal of social citizenship—with the exception of the United States, virtually all members of the Organization for Economic Cooperation and Development (OECD)—consider equally funded and free public education to be an essential component of their pursuit of equality of opportunity and hence of their welfare state in a broader sense.

WELFARE REGIMES

Beyond these shared traits, welfare states differ in many dimensions. Early classification schemes of the 1960s and 1970s, such as that of Harold Wilensky, ranked welfare states in linear fashion according to their “generosity” measured in only one dimension, aggregate spending levels. In 1990 Gøsta Esping-Andersen's groundbreaking book The Three Worlds of Welfare Capitalism proposed a new typology based on essential differences among welfare states that are not quantitative but qualitative. He preferred the term welfare regime, which focuses the analysis on the patterns of interaction of institutions governing primary and secondary distribution in the context of a nation's historically rooted political economy, to the term welfare state, which is typically viewed as working against or independent of market forces. First, welfare regimes differ according to their degree of "decommodification,” or "the degree to which individuals and families can uphold a socially acceptable standard of living independently of market participation” (p. 37); this dimension includes not only the benefit levels but also the eligibility terms and coverage levels of a country's social welfare schemes. Second, welfare regimes differ in terms of their
impact on social stratification, that is, their degree of redistribution, poverty reduction, and income equalization. Finally, they differ based on the priority given to the role of the state, market, and family respectively in protecting against welfare risks. Esping-Andersen's widely accepted typology distinguishes among three types of welfare regimes: liberal (e.g., the United Kingdom, the United States, Australia), social-democratic (e.g., Sweden, Norway, the Netherlands), or corporatist (e.g., Germany, Austria, Italy). Not only Esping-Andersen but also subsequent research on the "varieties of capitalism" by Peter Hall and David Soskice (2001) have demonstrated that a country's system of social protection forms an integral part of its political economy; thus a leading field of contemporary welfare research takes this holistic regime perspective, looking for institutional elective affinities between a country's variety of capitalism ("liberal," "coordinated," etc. [Hall and Soskice 2001]) and variety of welfare regime (e.g., Ebbinghaus and Manow 2001).

Liberal Regimes Of the three types of welfare regime, the liberal regimes redistribute income the least. Countries of this type provide minimum benefits to the poor and devote most of their expenditure to social-insurance schemes focused on the middle classes. The public schemes are not intended to be the beneficiaries' sole source of income in time of need, but instead to be a "safety net," or one pillar beside the second and third pillars of occupational plans and individual savings. In the liberal welfare world, individual performance in the market is considered to be the primary source of welfare, hence generous tax expenditures subsidize employee benefits and individual savings accounts in the pension and health areas. Citizens' welfare is commodified; they have weak or no constitutionally inscribed social rights, and high levels of socioeconomic inequality are tolerated. Citizens' welfare is best guaranteed, in the liberal worldview, through economic growth and opportunity rather than state provision; this is best achieved when minimal state taxation of private wealth fosters maximum investment and when minimal state benefits foster maximum self-reliance. Particularly in the United States, the more generous welfare states of Western Europe are viewed more as hammocks than safety nets, whereas the U.S. social net is seen by most Europeans as a sieve.

Conservative Regimes Conservative welfare regimes redistribute moderately, having as their main goals the preservation of social status achieved in the labor market and the realization of social citizenship rights. They provide equally funded and free public education, moderate benefits to the poor, and generous social-insurance schemes for employed persons, in which benefits are linked to contributions and both are linked to the income level attained. In the conservative welfare world, the family is considered to be the primary source of welfare. Hence both the tax system and social-insurance benefits are designed to support the family breadwinner.

Social-Democratic Regimes Social-democratic welfare regimes redistribute extensively and are by far the most successful in achieving long-term reductions in socioeconomic inequality, particularly across generations, as Walter Korpi and Joakim Palm demonstrate in their 1998 study. These regimes integrate antipoverty and social insurance programs in schemes open to all citizens. The schemes are designed to achieve decommodification, that is, to grant social citizenship—the right of meaningful participation in social life—independent of employment status. The state is responsible for achieving a considerable degree of distributional equality.

Although Esping-Andersen's typology still prevails in welfare state (or welfare regime) research, it has been criticized for overlooking certain dimensions. First, Ilona Ostner and Jane Lewis (1995) have pointed out that this hegemonic typology fails to account for gender discrimination in welfare states, most of which were based on the now-outdated male breadwinner model. Ann Orloff (1993) has developed a new welfare state typology based on the criterion of whether welfare states reinforce the traditional family system and women's inferior labor-force position or promote new, equal roles for both sexes. Second, in comparing Esping-Andersen's ideal-types to specific national experiences, many scholars have found the typology to be based too narrowly on the experiences of Britain, Germany, and Sweden and only partially applicable to other countries. In addition to ongoing debates about the classification of individual countries such as France, Ireland, or the Netherlands within Esping-Andersen's scheme, scholars have proposed supplementary ideal-types: Francis Castles and Castles and Deborah Mitchell (1993) distinguish an "antipodean" "wage-earners" welfare regime in Australia and New Zealand characterized by minimum wage legislation, compulsory arbitration and a protectionist consensus; Maurizio Ferrera (1996) and Giuliano Bonoli (1997) contend that a distinct Latin rim welfare regime (resembling the conservative one) exists in Italy, Spain, and Greece, where family and informal networks are important suppliers of welfare; Bob Deacon (2000), Nick Manning (2004), and Jolanta Aidukaite (2004) have documented the emergence of a postsocialist welfare regime (resembling the liberal one) in eastern Europe; and finally, some, such as Catherine Jones (1993) and Elmar Riegert and Stephan Leibfried (2003), have investigated and posited the existence of East Asian welfare regimes, based on "Confucian" values.
HISTORICAL ORIGINS
As the “logic of industrialization” school correctly observes, the historical origins of welfare state development lie in the consequences of the Industrial Revolution and attendant societal modernization—specifically, urbanization, industrialization, and economic liberalization—in the mid- to late nineteenth century. As Ferdinand Tönnies (2001) explains, these developments uprooted Western Europe’s inhabitants from premodern, static communities that had provided for mutualist social protection through the family, community, parish, feudal lord or guild, and thrust them into an individualized, comparatively anonymous urban society in which the satisfaction of basic needs was commodified, that is, had to be purchased with wages from employment. In the early decades of this societal modernization (from the late nineteenth century through World War I [1914–1918]), social unrest, epidemics, slum formation, violent labor conflicts, and radical political movements were rampant. Initially, bourgeois philanthropic associations attempted to mitigate this malaise but within a few decades realized they were overwhelmed. At the same time, the working classes’ sacrifice and service to their states as soldiers in the two world wars earned them sociopolitical recognition and rights in many European countries.

As Walter Korpi (1983, 1993) among others have noted, three factors converged to move political coalitions of bourgeois and working-class parties across Europe to grant workers social and political rights and institute generous welfare-state programs during the period 1918–1949: (1) workers’ newly won political power, organized in Social-Democratic and Labor parties and in some places accompanied by popular uprisings; (2) bourgeois elites’ fear of the political radicalization of impoverished workers as had occurred in the revolutions in Russia (the Soviet Revolution of 1917) and Germany (Adolph Hitler’s ascent to power in 1933)—a fear exacerbated by the Great Depression of 1929 to 1939 and by the witnessing of Hitler’s destruction of the Continent during the five years thereafter; and (3) strong national identities in newly unified nation states, forged and strengthened in the two world wars. Benjamin Veghte (2004) notes that in the United States, where the first two factors were largely absent, the working-class movement was much weaker and unable to achieve social citizenship rights for a variety of reasons. An ambitious welfare state (the New Deal) was introduced during this period, in 1935, but not based on social rights; rather, it largely excluded most of the poor population, such as agricultural workers and southern African Americans. Theda Skocpol’s research (1990) has revealed that the New Deal welfare state was not completely new, but rather followed in the footsteps of a generous Civil War pensions scheme that served millions of beneficiaries (Skocpol 1996). In Britain the Beveridge Report of 1942 highlighted the need for a welfare state to avoid the breakdown of society in the postwar period, and this became the blueprint for the welfare state introduced in postwar Britain.

PUBLIC-PRIVATE MIX
As noted above, prior to the formation of the modern nation-state, most types of social welfare were provided by collective, private forms of provision such as those offered by feudal hierarchies, guilds, and the church. In the course of urbanization, societal modernization, and the ascendance of liberal political and economic ideology since the late eighteenth century, free-market individualism underminded these traditional collectivist forms of private welfare provision, creating the modern “social question.” After the mid-nineteenth century, modern collectivist private welfare solutions such as solidaristic union/professional initiatives as well as bourgeois or church-based charitable ventures filled the vacuum, followed by welfare state initiatives from the 1880s in Germany, Belgium, and—since World War I—in most other Western nations. In most Western countries, then, since the mid-twentieth century the welfare state has been the primary instrument of welfare provision.

This has not been the case in many non-Western countries, however, nor in several liberal welfare regimes, most notably the United States. Interestingly, most countries with weak welfare states evoke high rates of religiosity and associated church-based welfare provision and religiously inspired philanthropy. As Leibfried and Mau note,

The history of religiosity in European and other countries which developed strong welfare states shows that the need for religious reassurance in one’s social existence has become less pressing when greater security is provided by the secular institutions of public policy. In other parts of the world, however, where state power has remained weak, the social institutions of religions—for example Islamic charities in Arabic countries, Hinduist castes in India and familial networks in East and Southeast Asia—remained the main provider of social security. (2007, p. xxv)

Secular welfare states may thus be viewed as functional alternatives to religiously inspired and/or organized private welfare provision. Empirically, as Pippa Norris and Ronald Inglehart (2004), and Elmar Rieger (2005) have observed, the revival of evangelical Protestantism in recent decades strongly correlates with the erosion of social security guarantees through the welfare state.

Non-profit, religiously inspired forms of welfare provision are not the only form of private provision to survive and thrive complementarily to and in tension with the
modern welfare state. Profit-oriented, market-based provision has done so as well, most strongly in the liberal welfare regimes of Great Britain, Switzerland, the United States, and Australia. These countries were pioneers in private, insurance-based provision, both for individuals and employees. Such welfare provision differs markedly from public provision in both its distributive dynamics (redistributing not across income classes but across the individual life course from economically self-sufficient to risky/dependent life phases) and its financial logic (calculated on actuarial rather than solidarity principles). This realm of social provision, much of which is subsidized by the government in the form of tax deductions (from the government’s perspective: “tax expenditures”), was overlooked in comparative welfare state research until the appearance of Martin Rein and Lee Rainwater’s (1986) pathbreaking analysis of the interplay of public and private welfare provision in OECD countries. Still today, however, most comparative research does not interpret the state-subsidized employee and individual benefits sphere, even though—as Willem Adema (1999, p. 30) and Jacob Hacker (2002, p. 338) have documented—in some countries such as the United States it makes up one-third of (public and private) social spending. Even Esping-Andersen’s (1990) research on the liberal welfare regime type, which theorizes the interaction between the state and the market, overlooks the magnitude and significance of private provision, thus misconstruing the U.S. system as “residual” and “means-tested.” Adema (1998, 1999, 2005) and Hacker (2002) have corrected this misinterpretation, pointing out that if U.S. employee and individual benefits are included in social spending data, the U.S. welfare system evinces a share of GDP roughly equal to the OECD average. The key difference between public (direct) and private (tax expenditure) welfare state expenditure is that the former tends to be redistributive and focus on alleviating poverty, whereas the latter focuses on helping the middle classes provide for their own economically precarious life episodes.

THEORIES OF DEVELOPMENT

In the 1960s and early 1970s, the best comparative work on the welfare state found a country’s prevailing political culture—often termed national values—to be causally significant in shaping its welfare state institutions and their degree of generosity (e.g., Rimlinger 1966, 1971). This ideational approach was displaced in the 1970s by functionalist and modernization theories, most prominently that of a “logic of industrialization” (Wilensky 1975). In light of the universal dissolution of pre-modern mechanisms of social protection—namely, the family, church, feudal hierarchy, guild and local community—all industrializing countries faced similar social problems, and hence developed similar modern instruments to secure a healthy and productive workforce. In this view, differences in welfare state spending levels are attributable not to political-cultural or other qualitative cross-national differences, but to a country’s level of economic development as well as the age structure of its population and degree of maturation of its welfare state. Ultimately, the school claimed, all countries would converge toward an institutionally similar, generous welfare state. Since the 1980s, power-resources as well as polity-centered (and closely related new-institutionalist) explanations have proven more convincing. The power-resources approach, articulated by Korpi (1983) and Evelyne Huber and John Stephens (2001), argues that the social and political balance of power between labor and capital has determined the level of spending and in particular the degree of redistributiveness of welfare states. Research on the correlation between the partisan composition of governments and their levels of welfare state expenditure has largely corroborated the power-resources interpretation: Manfred G. Schmidt (1982, 1996), Castles and Herbert Obinger (2007), and indeed recently also Wilensky (2002) himself have found strong statistical evidence that where left-of-center (“social democratic,” “labor” or “democratic”) parties have ruled, levels of government social spending and redistribution have been much higher on average than in cases where right-of-center, free-market-liberal (“liberal,” “conservative,” or “republican”) parties have reigned. This “parties matter” explanation enriches the power-resources interpretation, moreover, by showing that the left-right dichotomy does not explain partisan influence fully: Christian-democratic and center parties, historically common in continental Europe, correlate with moderate social spending, that is, more generous than the free-market-liberal parties and less generous than the leftist parties.

Willem Adema and Maxime Ladaique (2005) have demonstrated that when the tax system and private benefits are also taken into consideration, liberal welfare regime expenditure approximates that of the other two regime types. This suggests that Wilensky’s “logic of industrialization” explanation of welfare state growth was correct, according to which a high level of economic development has driven all Western countries to converge toward a uniform, generous welfare state. Castles and Obinger (2007) rebut Adema and Ladaique, however, arguing that while the much greater private welfare spending of liberal welfare regimes often puts them on a par with conservative and social-democratic welfare regime expenditure, the latter are far more redistributive across income categories, making for a fundamentally different type of welfare state. Regarding the causes of welfare state development, they find that while the levels of economic development and economic growth best explain the increase in overall (public and private) welfare spending,
power resources—measured in terms of partisan incumbency—best explains the growth in the more redistributive, direct state welfare spending.

The polity-centered and new-institutionalist approaches adamantly dispute the explanatory power of class. They attribute the scale and type of welfare state expansion and retrenchment to state-structural factors such as the nature of the party system and civil service and the influence of policy intellectuals and reformist associations on these, as in the work of Skocpol (1985); Margaret Weir, Orloff, and Skocpol (1988); and Dietrich Rueschemeyer and Skocpol (1996); the lack of constitutional “veto points,” as in the work of Ellen Immergut (1989) and George Tsebelis (2002); and “feedback effects” of (pre-)existing institutions and policies, as in the work of Paul Pierson (1993).

Both theory and comparative data on public opinion on the welfare state have improved since the 1990s, giving ideational approaches an empirical basis and rendering them worthy of causal reconsideration alongside the power-resources and new-institutionalist explanatory approaches. Indeed, Clem Brooks and Jeff Manza (2006) have found that national social policy preferences exert a strong and measurable influence on welfare state spending as well as on cross-national variation therein, after controlling for other factors such as institutional feedback effects. Mau and Veghte (2007) find strong relationships between welfare regimes and social policy attitudes across OECD countries. Further, Veghte, Greg M. Shaw, and Robert Y. Shapiro (2007) have revealed that social policy preferences and issue prioritizations themselves are contingent and malleable in response to issue framing—for example, of military over social security—by political elites. Given the availability of new transnational datasets on both public opinion and party platforms, more research into public opinion on welfare state issues and its relation to the aforementioned causal factors, and incorporation of this dimension into welfare state theory, can be expected.

SOURCE OF FUNDING

Scholars used to distinguish between contribution-based (the Bismarckian, German model) and tax-based (the Beveridge, English model) funding of welfare state programs, but in practice these two models have converged, as most social-insurance schemes are funded by a mixture of employer/employee contributions and subsidies from general state revenues. Contribution-based schemes, which are funded and administered independent of the government budget and in which members have vested benefits, have historically tended to be more generous and less susceptible to retrenchment than tax-funded schemes, which legislators can cut back when tax revenues are scarce or an antiwelfare state party comes to power.

WELFARE STATE CRITIQUE AND REFORM

After expanding steadily during the “Golden Age” of welfare-state development in the 1960s and early 1970s, most Euro-American welfare states suffered a critical shock from the oil crises and recession of the mid-1970s and the deindustrialization and high unemployment rates that followed. Not only did these factors deprive the welfare state of its financial bases in both tax revenues and employer/employee contributions, the welfare state itself was widely considered to have contributed to the economic collapse by draining the economy of investment income and burdening it with bureaucratic regulations, as well as undermining individual initiative and the will to work through excessive benefits that fostered dependency. Further, the decline in industrial and the rise in service sector employment, as well as increasing individualization, disintegrated the working classes, which historically had directly or indirectly been the main driving force and constituency of welfare state development in all OECD countries except the United States. Overall, the rapid and sharp rise in the absolute and relative amount of government spending devoted to the welfare state, together with the declining popular support for the latter, led many observers by the mid- to late 1970s to perceive a “crisis of the welfare state” (Flora 1981; Ofie 1984). If some degree of retrenchment were not implemented, the welfare state threatened to bring Western economies to a standstill. Conservatives won national elections in Britain (Margaret Thatcher), the United States (Ronald Reagan), and West Germany (Helmut Kohl), in the early 1980s and were reelected in the mid-1980s, all running on anti-welfare-state platforms. Ever since, conservatives in most other OECD countries have tried to scale back welfare-state benefits as well as restrict eligibility to those “truly in need.” This has proven extremely difficult, given that in democratic systems, once citizens and/or interest groups have acquired benefits, they mobilize strongly to retain them. As Pierson observes, “Retrenchment is generally an exercise in blame avoidance rather than ‘credit claiming.’” First, the costs of retrenchment are concentrated, whereas the benefits are not. Second, there is considerable evidence that voters exhibit a “negativity bias,” remembering losses more than gains. As a result, retrenchment initiatives are extremely treacherous” (1994, p. 18). Due to this “conservative welfare function” (Rieger and Leibfried 2003), benefits in most welfare states (with the exceptions of New Zealand and Switzerland) have been scaled back very little in OECD countries despite extended periods of neoliberal governance.

What welfare state reformers have been able to achieve is a tightening of eligibility criteria, moving away from the model of the welfare state as provider of benefits to persons unable to work and toward an activating wel-
fare state that provides an incentive to work by targeting benefits (and/or providing more generous benefits) to persons working or actively seeking employment, while further decreasing the number of inactive citizens by scaling back employment and wage regulation and postponing the retirement age.

Many scholars have also criticized the welfare state for its focus on the male breadwinner and the attendant discriminating effects on social groups long denied equal opportunity in the labor market, such as women, ethnic minorities, and the disabled. Feminist scholars have called attention to the fact that such welfare-state subsidizing of the higher earner (breadwinner) in a family, particularly pronounced in conservative welfare states, reinforces the gendered division of labor within the family. Others have criticized citizenship requirements in many welfare state programs for their discriminatory effects on noncitizens, who are in most cases ethnic minorities.

**TRENDS IN THE EARLY TWENTY-FIRST CENTURY**

The most important developments affecting welfare states are not their internal dynamics but changes in their fiscal, economic, and societal environments. Over the past quarter century, deindustrialization has brought about a dramatic and enduring decline in the proportion of skilled middle-class workers, transforming many of them from employees who pay into the system into long-term unemployment beneficiaries—especially in the conservative welfare regimes of continental Europe, with their generous unemployment schemes.

At the same time as these costs have risen, since the 1990s economic globalization has given new credibility to threats by the owners of capital to leave countries that tax corporations and/or wealthy individuals excessively (Genschel 2005), placing strong external restrictions on the national welfare states to finance themselves through taxation. Further, as Jef van Langendonck (1997), Esping-Andersen (1999), and Peter Taylor-Gooby (2004) have shown, the demographic challenges of population aging and a vast increase in single-parent families have created new social risks which the traditional welfare state—based on the male breadwinner—was not designed to handle. As a result of these developments, most welfare states have experienced a decline in contributions and an increase in demand for benefits, posing a formidable challenge to their sustainability and suggesting the need for welfare state reforms to adapt to these new social conditions.

The main response to this second crisis of the welfare state since the late twentieth century has been privatization. Such privatization entails three principle shifts: first, from publicly guaranteed outcomes to defined contributions; second, from mandatory to voluntary provision against future risks; and third, from the group solidarity to the individual actuarial principle. Such privatization promises to lessen the fiscal burdens incurred by public social insurance schemes for the health and pension needs of the imminently retiring baby boom generation by increasing copayments and restricting eligibility and benefits, while simultaneously offering all individuals the opportunity to save individually for their future security needs via tax-deductible contributions to publicly regulated, individual private pension plans. This should also lessen the burden on corporations posed by the non-wage labor costs entailed in employer and employee contributions to public social-insurance schemes, increasing the international economic competitiveness of Western economies in the era of globalization. The biggest disadvantage of such privatization is that it necessarily entails a shift from universal to partial coverage of the population in need, with a tendency to exclude precisely those who need social protection the most, because they lack the surplus income required to voluntarily save for their and their families’ future risks. Finally, corporations, which have long provided tax-deductible employee benefit plans to their employees, have moved from defined benefit to defined contribution plans, i.e. from occupational pension plans which guarantee a specific payout in retirement based on a formula for years of service and salary earned, to plans which collect employer and employee contributions in interest-bearing individual retirement accounts which are transferable from one job to the next, but may or may not suffice to meet—in combination with one’s public pension—a person’s retirement needs.

A final challenge to the welfare state at the outset of the twenty-first century is posed by immigration. As Wim van Oorschot (2000), Michael Bommes and Andrew Geddes (2000), Carsten Ullrich (2002), Knut Halvorsen (2007), and van Oorschot and Wilfred Uunk (2007) have shown, national solidarity communities that long provided the normative foundation for European welfare states are now being threatened by real and/or perceived increases in ethnic/national heterogeneity, as evidenced by political debates throughout western Europe in the first decade of the century. Regarding the United States, Korpi (1983), Martin Gilens (1999), and Vegte (2004) have argued that racial, ethnic and religious heterogeneity have always limited development of a solidarity community and hence a redistributive welfare state. Now, scholars such as Alberto Alesina and Edward L. Glaeser (2004) are asking if, as citizens increasingly tend to distinguish between “we” and “they,” the welfare consensus and commitment to publicly institutionalized solidarity in western Europe is still sustainable. Keith Banting and Will Kymlicka (2004) have determined, however, that clear evidence of a negative association between the influx of migrants and support for the welfare state is lacking. The
structure of countries’ political institutions mediates and conditions the effects of immigration on welfare state development, and at the cross-national level other factors are likely more decisive. Nevertheless, as Leibfried and Mau (2007) observe, politicians may use ethnic and sociocultural divisions within a society to position themselves in public debates about distributional conflicts, leading to restrictive effects on welfare state policies.

While the threats from increasing immigration seem formidable, most welfare states are showing signs of successful adaptation to the challenges posed by economic globalization. Comparative research by Fritz Scharpf and Vivien Schmidt (2000) on the effects of globalization on Western welfare state development has revealed that welfare regimes differ in their capacity to adjust to the fiscal and competitiveness constraints constituted by increasing global product and capital market integration. Social-Democratic and liberal welfare regimes in Scandinavian and Anglo-American countries respectively, though fundamentally different, have proven better suited to successful adaptation to the challenges of economic globalization than have the conservative welfare regimes of continental Europe.

Moreover, Elmar Rieger and Stephan Leibfried (2003) argue convincingly that strong welfare states will not only survive the era of globalization, but have themselves historically paved the way for it. Since World War II (1939–1945) and continuing under conditions of intensified economic globalization since the 1990s, strong welfare states have provided political leverage in capitalist democracies such as Germany for leaders to embrace exposure to the risks of international competition in foreign economic policy, whereas countries with weak welfare states such as the United States have tended toward protectionism. As Sven Steinmo (2002) has shown, the Swedish case in particular demonstrates that a generous welfare state, with some recalibration over the past decade, can co-exist over the long term with a thriving, open and internationally competitive national economy.

A half century ago, one of the fathers of modern social policy, the Swedish Nobel prize-winning economist Gunnar Myrdal (1898–1987) argued that a transition from the welfare state to a “welfare world” would eventually transpire. Today, a budding field of welfare state research—pioneered by Deacon, Michelle Hulse, and Paul Stubbs (1997); Nicola Yeates (2002); Lutz Leisering (2004); and John Meyer (2004)—and pursued in the journal, _Global Social Policy_ (launched in 2001)—traces the emergence of “global social policies” emanating from supranational and global nongovernmental organizations and governmental institutions such as the ILO, World Bank, World Trade Organization, or United Nations. At the crossroads of the “world society,” international relations, welfare state and area studies literatures, this research examines how welfare concepts, programs, and models are becoming globalized.

Many eminent welfare state scholars, however, such as Abram de Swaan (1997), Claus Offe (2003), Fritz Scharpf (1999, 2002), and Wolfgang Streeck (1995, 2000), are skeptical concerning the prospects of transnational social policy. Historically, as Stein Rokkan elaborated in his seminal 1974 essay, welfare states have developed in the wake of processes of state-building, nation-building, and democratization, that is, in democratic nation-states. This process took several centuries to evolve and was a rocky road paved by multiple wars and, in many countries, revolutions. Transnational social policy is unlikely to develop until something equivalent to the public sphere and solidarity community of the nation-state evolves on the transnational level, that is, a shared willingness to redistribute income across national boundaries.

The closest thing to such a transnational polity and solidarity community on the horizon is the European Union, formerly the European Community. For the first four decades of its existence, the European Community pursued economic integration without political or social integration. Since the last decade of the twentieth century, however, the European Union is slowly but discernibly moving toward such political and social integration, yet, as Franz-Xaver Kaufmann (2001) has noted, continues to evince a strong reticence with regard to all issues of interpersonal income redistribution. Leibfried (2005) and Obinger, Leibfried, and Castles (2005) observe that rather than employing centrally administered, mandatory, redistributive “hard” social policies, as national welfare states had done, the European Union has relied thus far on courts and markets and on “soft policy,” that is, governance measures with which compliance is not enforced by legal sanctions, but simply encouraged through the “open method of coordination.” As Leibfried and Mau (2007) have observed, beyond its borders Europe is the leading advocate of transnational social policy as propagated by global institutions such as the WTO, the WHO, and ILO, and may one day serve as an organizational model inspiring for example the NAFTA, MERCOSUR and ASEAN countries to pursue transnational social policies in their respective regions. The debates on the evolution of European social policy can be followed above all in the _Journal of European Social Policy_ (since 1991) and increasingly in the _Journal of European Public Policy_ (since 1994), which explores the interaction between central and nation-state social policy in the European Union.

WELLS-BARNETT, IDA B.
1862–1931

Ida Bell Wells-Barnett gained a national reputation in the 1890s as a pioneering crusader against lynching. Her long career spanned a wide variety of venues, including schoolroom, settlement house, municipal court, electoral politics, home, church, and social club. Journalism, however, was her calling. Her publications, many of them too militant or sharply worded to find a substantial receptive audience, remain her greatest legacy.

The eldest of eight children, Ida was born into slavery in Holly Springs, Mississippi, fifty miles southeast of Memphis. Her parents died in the yellow fever epidemic that swept through the Mississippi River Valley in 1878, leaving sixteen-year-old Ida to care for five siblings. She quickly secured a teaching position, made possible by her education at Shaw University in Holly Springs. Between 1880 and 1882 she relocated to Memphis, taking along two sisters and leaving her other siblings in the care of relatives.

Wells found her teaching career in Memphis unsatisfying, and she soon discovered a far more rewarding form of pedagogy: journalism. She published her first newspaper article in a church weekly in 1883, and began sending articles about black women to major African American publications in eastern cities. By 1885, writing as “Iola,” she was among the few African American women writing about politics, and in 1889 she became co-owner of the Memphis Free Speech and Headlight. Her straightforward criticism in 1891 of the Memphis school board’s neglect of black children and exploitation of black female teachers led to a decision not to renew her teaching appointment.

Wells’s uncompromising journalism reflected her general approach to race relations. At the age of twenty-two, she sued a railroad after being thrown off the train for refusing to ride in a segregated car. In 1892 three Memphis black grocers were lynched after a conflict with a white competitor envious of their success. Wells later recalled that the event “changed the whole course of my life” (DeCosta-Willis 1995). Her unsigned attack on the lynching eschewed the cautious convention observed by southern black spokesmen who paired their criticism of lynching with ritualized reminders that the black community should not accept criminal behavior within its ranks. Wells understood that lynching was meant less to punish depravity (which white southerners expected from “their Negroes”) than to punish the more dangerous sin of a black person not accepting his place.
Wells left Memphis immediately, probably expecting the mob attack on her newspaper the following day. She spent the next three years in eastern cities and Great Britain, lecturing and writing (now under the name “Exile”). Drawing on statistics compiled from careful research, she demonstrated that less than a third of lynching victims had even been accused of rape. Lynching, she argued, had less to do with the honor of white womanhood than “an excuse to get rid of Negroes who were acquiring wealth and property and thus keep the race terrorized and ‘keep the nigger down’” (DeCosta-Willis 1995, p. xiii). Her charge that liaisons between white men and black women constituted the true threat to racial purity stirred even greater controversy.

Wells visited Chicago in 1893 to protest the exclusion of African Americans from the World’s Columbian Exposition. Characteristically, she took a more militant position that most of her peers, advocating a boycott of the “Colored American Day” granted by the fair managers to placate the protesters. She relocated to Chicago permanently two years later, marrying prominent attorney Ferdinand Barnett. Over the next three decades she wrote less, putting her energies into the woman suffrage movement, local politics, and social work. In 1910 she founded the Negro Fellowship League as a venue for “missionary work” and “social work” on the city’s South Side. Facing competition first from the city’s black YMCA (1913) and then Urban League (1915), the Fellowship League shifted to a focus on politics and had only a minor presence by the time black southerners began moving to Chicago in large numbers in late 1916.

Wells-Barnett, who attended the founding meeting of the NAACP in 1910 in New York, never established herself as a major figure in African American institutional life. Although conventionally middle class in style, manners, and religious observance, she had limited patience with polite diplomacy during a generally cautious era of black politics.

Although she effectively mobilized black voters briefly through the Alpha Suffrage Club (established in 1913), Ida B. Wells was more adept at analytical and rhetorical provocation than organization. She understood in the 1890s what W. E. B. Du Bois (1868–1963) would famously enunciate four decades later in Black Reconstruction (1935): that African American success and dignity were less likely to win equal citizenship than to provoke the violence necessary to keep “the Negro” in his place.

WELTANSCHAUUNG

Weltanschauung is a German word that often is translated as “worldview” or “world outlook” but just as frequently is treated as a calque or left untranslated. A Weltanschauung is a comprehensive conception or theory of the world and the place of humanity within it. It is an intellectual construct that provides both a unified method of analysis for and a set of solutions to the problems of existence. The concept of a Weltanschauung has played an important role in the development of psychoanalysis, critical theory, and nineteenth- and twentieth-century hermeneutics.
Weltanschauung is connected closely to the work of Wilhelm Dilthey (1833–1911), who wanted to provide for the human sciences what Immanuel Kant (1724–1804) had provided for the natural sciences. Kant had established the possibility of objective and certain knowledge for natural science (Naturwissenschaft) in his Critique of Pure Reason (1781). Dilthey intended to fashion a critique of reason on behalf of the historical human or cultural sciences (Geisteswissenschaft). For Dilthey the goal of natural science was causal explanation, whereas the goal of human sciences was to achieve understanding by means of interpretation. Every interpretation, he reasoned, takes place within a larger understanding of the world (i.e., a Weltanschauung), which itself is historically conditioned. Thus, interpreters of human history and culture must recognize their immersion in a particular historical situation and tradition and in that process come to terms with the finitude of their perspective. The irony of Dilthey's historicist conclusions lies in the fact that they undermine his original goal of establishing universal validity for judgment in the human sciences. This split or contradiction resulted in differing orientations to the concept of the Weltanschauung among thinkers such as Freud, Husserl, Heidegger, and Gadamer.

For Sigmund Freud (1856–1939) the age of modernity was the coming into being of the rational or scientific Weltanschauung and the subsequent decline or eclipse of alternative religious or philosophical Weltanschauungen. The scientific Weltanschauung sees both the natural world and the cultural world as being ultimately transparent to the power of human cognition. Therefore, it consciously supplants world outlooks that place certain phenomena beyond the reach of human understanding. In Freud's view psychoanalysis represented the last contribution to the criticism of nonscientific Weltanschauungen (for instance, by tracing the origin of religion to the persistence of the wishes and needs of childhood into maturity). The arrival of the scientific Weltanschauung, which Freud described as still being in its infancy, would resolve the paradox left behind by Dilthey. This was a historically conditioned view of the world, but because it represented the endpoint or terminus of human cognition, it could provide objective and certain knowledge for all human activities and endeavors.

A more direct successor to Dilthey was Edmund Husserl (1859–1938). In rejecting the strong claims of scientific rationalism, Husserl argued that objects are experienced by the observer only from within an intentional horizon of consciousness, or “life-world” (Lebenswelt). In other words, objects are not located in objective or autonomous space and time; they do not exist outside a detached observer who can come to know them objectively and finally. For Husserl meaning does not exist “out there” but resides only where subject and world meet. The goal is to strip away the preconceptions of history and science so that consciousness can understand the object as it really is.

Husserl, however, like Freud, ignored the historical nature of Dilthey's account. The very possibility of ahistorical meaning was challenged by Husserl's successors in phenomenology and hermeneutics, including Martin Heidegger (1889–1976) and Hans Georg Gadamer (1900–2002).

Heidegger emphasized the finitude of all historical and cultural interpretation at the expense of ahistorical accounts. For Heidegger hermeneutics, as the theory and practice of interpretation, must remain cognizant of different Weltanschauungs operating in certain historical contexts. One can know an object only from within one's peculiar and historically conditioned Weltanschauung or (Heidegger's favored term) Weltbild (world-picture). As interpreters of the world around them, people always find themselves within a particular language and culture. People cannot bracket the presuppositions of their Weltanschauung in order to explicate reality; in fact, those presuppositions become part of the very existence that demands explication.

Hans-Georg Gadamer, whose 1975 work Truth and Method represents the major thrust of contemporary hermeneutics, extended the Heideggerian critique of ahistorical interpretation in many ways. For Gadamer understanding involves an interpretive dialogue with the Weltanschauung in which one finds oneself. People's modes of understanding (their “methods”) are at one and the same time the means of interpretation and objects that require interpretation. Gadamer reconnects to the historicist conclusions of Dilthey with his assertion that understanding can be achieved only with reference to the Weltanschauung in which that understanding is taking place. Unlike Dilthey and Heidegger, however, Gadamer posits that there can be no final interpretation of reality because new life-worlds or world pictures will cause future interpreters to see and experience the world differently.

A GROWING PHENOMENON

In the late twentieth century and the early twenty-first century the extent of whistle-blowing grew greatly, with studies reporting substantial cases in Canada, Australia, South Africa, the United Kingdom, and Europe in addition to the United States, and worldwide attention paid to whistle-blowers in the mass media has been expanding. One analysis of previous research studies of whistle-blowing in the United States found that approximately 37 percent of employees observe in their workplaces some type of wrongdoing that troubles them (Miethe and Rothschild 1994). This rate, however, can vary considerably by occupational grouping. Among internal auditors, people who are trained to discover financial fraud and whose jobs require them to look for it, 82 percent say they have observed wrongdoing (Near and Miceli 1985). A large survey of federal employees found the rates of observing misconduct to range from 7 percent to 45 percent, depending upon the agency and the occupation involved (U.S. Merit Systems Protection Board 1993). The proportion of those who say they have observed serious misconduct in the workplace varies greatly by the opportunity for such observation in one's occupation.

Of those who do say they have observed misconduct, most remain silent, although this too can vary considerably by country, occupation, and type of employer. Across six U.S. studies of employers, the average rate of silence among those who said they did observe serious misconduct in their places of work was 58 percent (Miethe and Rothschild 1994), while a later international review of the research literature shows that the rate of those who remain silent can vary from 25 percent to 91 percent (Maria 2006). These numbers imply that there is considerable room for growth in this whistle-blowing phenomenon if more individuals felt free to voice their concerns. Undeniably, interviews with these silent observers indicate two main reasons so many employees hold back from voicing their concerns at work: (1) they fear retribution from their employer, and (2) they suspect that their reportage would not effect organizational change in any case (Rothschild and Miethe 1999).
THE WHISTLE-BLOWER’S EXPERIENCE

Research findings quite clearly show that observers of misconduct do put themselves in jeopardy by reporting or disclosing the misconduct, whether they stay inside the organization or go outside the organization with their disclosures. Indeed, employer retaliation against whistle-blowers is the rule, not the exception, and some whistle-blowers are so devastated by the reprisals they suffer that they cannot reclaim their lives (De Maria 1999; Alford 2001). A nationwide study of whistle-blowers from all occupations and regions of the United States found that among those employees who stayed within their employing organization, reporting their observations and concerns only to those above them in the organizational hierarchy, the following occurred as a result of their disclosures:

- 69 percent were fired or forced to retire from their jobs,
- 64 percent saw their job performance evaluations decline abruptly,
- 68 percent had their work more closely monitored by supervisors,
- 64 percent felt they had been blacklisted from getting another job within their field.

For each of these items, the rate of retaliation was 10 to 15 percentage points higher for those who went outside of the employing organization with their concerns (Rothschild and Miethe 1999). In many cases, the reprisals that follow the reportage are experienced as traumatic. Some 84 percent said the experience gave rise to “severe depression or anxiety,” 78 percent said they learned from it “distrust of others,” 69 percent said they suffered a “decline in physical health,” 66 percent said they suffered “severe financial decline,” and 53 percent said the experience harmed their “family relations.” Many former whistle-blowers describe their experiences as giving rise to a political and personal transformation by which they now see themselves as exceedingly moral and their former employers (and in many cases, large organizations in general) as corrupt (Rothschild and Mierhe 1999).

Statistical analysis of the data indicates that no special gender, age, educational attainment, years of employment, or method of reporting can insulate individuals from organizational retaliation should they choose to disclose the organizational misconduct. Validity of the claim also provides no insulation. Indeed, the data show that retaliation against whistle-blowers is most severe and certain when the observed wrongdoing is systemic and central to the way the organization conducts its business and accumulates its profit (Rothschild and Miethe 1999).

FEDERAL AND STATE LAWS

Federal and state laws that would protect whistle-blowers from retaliation and that would thereby encourage the disclosure of organizational practices that injure the public are not comprehensive, and even where they do seem to be applicable, they are frequently not enforced (see Government Accountability Project 1996 for a review of these). It is not easy for the whistle-blower, generally unemployed, to mount a successful legal claim against a former employer with vastly greater legal resources. The Sarbanes-Oxley Act of 2002 provides the most substantial legal protection for whistle-blowers, but it applies only to those who would disclose corporate misconduct that, if proven, would materially affect the valuation of a publicly traded company. The qui tam suits filed under the provisions of the False Claims Act have proven most effective at gaining large awards for whistle-blowers, but this act applies only to those employees whose employers were defrauding the federal government, again covering only a portion of the potential whistle-blowers.

As organizations grow larger in scope and more complex operationally, effective oversight from outside agencies becomes more difficult, and often the only people who are in a position to detect when the organization is defrauding or endangering the public are key employees themselves. The U.S. Congress has recognized the public’s interest in protecting whistle-blowers so abuses of the law or the public trust can come to light, and parliaments in other nations have recognized the same. But the extent of persistent retaliation against whistle-blowers and the extent of employees who choose to remain silent in the face of abuses at work suggests that more needs to be done.

WHITE, WALTER
1893–1955

Walter White, author and chief executive of the National Association for the Advancement of Colored People (NAACP) between 1929 and 1955, was born in Atlanta, Georgia. According to the New York Times obituary of March 22, 1955, “Mr. White, the nearest approach to a national leader of American Negroes since Booker T. Washington, was a Negro by choice” (p. 31). White had blond hair, blue eyes, and a complexion that was light enough to “pass” for white. But if ever White questioned his racial identity, the 1906 Atlanta race riot made clear to him that he was African American. During this pogrom, a white mob threatened to attack his family home, and at the age of thirteen he determined that he could never be part of a race that carried within it such a ghastly hatred. His aspect and the riot were central to his life and career as an advocate for race advancement.

Upon his graduation from Atlanta University in 1916, White helped to found the Atlanta branch of the NAACP. He joined the national staff in January of 1918, and for the next eight years his primary responsibility was conducting undercover investigations of lynchings and race riots. He investigated forty-one such instances. Passing for white, White tricked whites into giving him candid accounts of the recent violence, which the NAACP would then publicize. “I Investigate Lynchings,” which appeared in the July 1929 issue of American Mercury, is White’s account of his investigative exploits. Rope and Faggot, published in 1929 and still considered authoritative, is his detailed analysis of the extent and causes of lynching.

When James Weldon Johnson (1871–1938) retired from the NAACP in 1929, White was elevated to the position of secretary. During both the Franklin Roosevelt (1882–1945) and Harry Truman (1884–1972) administrations, White’s style of working for political gain by ral-lying enlightened elites achieved stunning results. His close friendship with Eleanor Roosevelt (1884–1962), who joined the NAACP board of directors following her husband’s death, gave him direct access to the White House. He orchestrated massive support in Congress for an antilynching law, which was defeated only by filibustering southern Democratic senators. White also organized Marian Anderson’s (1897–1993) historic Easter 1939 concert at the Lincoln Memorial in Washington, D.C., including a sponsoring committee studded with New Deal officials. In 1941 White collaborated with A. Philip Randolph’s (1889–1979) March on Washington movement, which pressured President Roosevelt into issuing Executive Order 8802 banning racial discrimination in defense industries. White persuaded President Truman to appoint a civil rights commission, which produced the report To Secure These Rights in 1947.

During White’s tenure as NAACP secretary, the association launched a series of legal suits designed to ensure equality between the races in education. This effort culminated in the Supreme Court’s 1954 Brown v. Board of Education decision, which declared unconstitutional the doctrine of “separate but equal.”

During World War II (1939–1945), White promoted the idea that an allied victory should lead to both the dismantling of European colonialism and racial equality for African Americans. He pursued these goals in 1945 as one of three NAACP consultants to the U.S. delegation to the founding conference of the United Nations in San Francisco and again in 1948 as a consultant to the U.S. delegation to the UN General Assembly meeting in Paris. Yet his friendship with Eleanor Roosevelt and alliance with President Truman precluded White from advocating the more expansive definition of human rights favored by W. E. B. Du Bois (1868–1963) and Paul Robeson (1898–1976) that included economic and social as well as political rights.

White’s twenty-six year marriage to Gladys Powell, an African American, ended in divorce in 1948. The following year he married Poppy Cannon, a white woman born in South Africa. Many in the NAACP objected and called for White’s resignation. Eleanor Roosevelt threatened to resign from the board of directors should White be dismissed, thereby saving his position. He remained NAACP executive secretary until his death (he had been in declining health for several years) but with diminished powers.

Walter White’s importance lay in his organizational skills and leadership style. His abilities to successfully cultivate ties with people of influence both in and out of government and to popularize and publicize the association and its program were instrumental to placing civil rights on the national agenda.

Kenneth R. Janken

**WHITE NOISE**

There are uncertainties in dynamics of social and natural processes. Basic approaches of statistical analysis model these processes based on theoretical derivations or empirical observations. The primary goal in statistical modeling is to extract as much underlying information of the processes as possible and let the residuals approximate a realization of white noise. White noise is one of the fundamental stochastic processes in many fields. Mathematically, it has a constant spectrum, which is the same as the white light we observe through our eyes.

White noise has been utilized to mask distraction of undesirable sound in the environment. Financial analysts have applied white noise to model stock markets. In fact white noise has been used for audio synthesis, impulse response, art, sensory deprivation, sleeping aid, and more. White noise is a basic form of stochastic process that provides the foundation for almost all useful statistical models used in natural and social sciences.

Let \( \{Z_t\} \) be an equally spaced time series (a sequence of random variables) with a mean of zero and finite autocovariance

\[
\gamma(t, s) = E(Z_t Z_s),
\]

where \( E(X) \) is the expected value (mean) of random variable \( X \) and \( t, s \) donate the time. If \( \{Z_t\} \) has a nonzero mean, without loss generality, it can be subtracted from the time series to get a time series with a zero mean. The expected value of a discrete random variable \( X \) is defined as

\[
E(X) = \sum_{x} x P(X = x),
\]

where \( P(X = x) \) is the probability mass function of \( X \). For a continuous random variable, its expected value is

\[
E(X) = \int_{x} x f(x) dx,
\]

where \( f(x) \) is the density function of \( X \).

If the autocovariance function \( \gamma(t, s) \) of time series \( \{Z_t\} \) is only a function of \( |t - s| \), then \( \{Z_t\} \) is a (weak) stationary process. White noise is the simplest stationary process with

\[
\gamma(t, s) = \begin{cases} \sigma^2 & t = s \\ 0 & t \neq s \end{cases}
\]

where \( \sigma^2 = E(Z_t^2) \) is the variance of \( Z_t \).

White noise plays an important role not only in physical sciences such as in signal processing, but also in almost all statistical analysis of time series observed from social and economic activities. For example, according to George Box, Gwilym M. Jenkins, and Gregory C. Reinsel in their 1994 book *Time Series Analysis: Forecasting and Control*, the widely used Autoregressive and Integrated Moving Average (ARIMA(p,d,q)) models in time series analysis are generated by the white noise innovations \( \{Z_t\} \) through the following expression:

\[
\phi(B)(1 - B)^d Y_t = \theta(B)Z_t
\]

where \( Y_t \) is the time series under study, \( \varphi(B) = 1 - \sum_{l=1}^{p} \alpha_l B^l \), \( \theta(B) = 1 + \sum_{l=1}^{q} \beta_l B^l \), \( B \) is the back shift operator defined as \( BY_t = Y_{t-1} - Y_{t-d} \), \( d \) is an integer, and \( Z_t \) is the Gaussian white noise with mean zero and variance \( \sigma^2 \). From expression (5) we can see that \( Y_t \) of ARIMA(0,0,0) is the white noise.

ARIMA(0,1,0) denotes a random walk model, which is a model of unit root and widely used in modeling financial markets. ARIMA(p,0,0) becomes an autoregressive model of order \( p \) (AR(p)), ARIMA(0,0,q) is a moving average model of order \( q \) (MA(q)), and ARIMA(p,0,q) is ARIMA(p,q). For a proper range of the parameters \( \alpha_l \) and \( \beta_l \), the \( Y_t \) in ARIMA(p,q) is stationary and invertible (Box, Jenkins, and Reinsel 1994).

Many methods have been proposed to estimate the parameters in ARIMA models from observed time series. A crucial step in model diagnosis is to check, through a battery of tests and plots, if the residuals from the models are consistent with white noise (Box, Jenkins, and Reinsel 1994).

In general there are two types of techniques in analyzing time series. The first type is based on direct modeling such as ARIMA models, which are called time domain techniques (Box, Jenkins, and Reinsel 1994). The second type, according to M. B. Priestley in the 1981 publication *Spectral Analysis and Time Series*, is in the frequency
domain that utilizes the spectrum of a stationary process. The spectrum is defined as

\[ f(\omega) = \sum_{k=-\infty}^{\infty} \gamma_k e^{-ik\omega} = \gamma_0 + 2 \sum_{k=1}^{\infty} \gamma_k \cos(k\omega) \]  

where \( \gamma_k = \gamma(t, t + k) \) and \( i = \sqrt{-1} \). For a stationary ARMA\((p,q)\) process, the spectrum is \( f(\omega) = \sigma^2 |\theta(e^{j\omega})| |\varphi(e^{j\omega})|^2 \), where \( \| \| \) is the norm of a complex number.

For white noise, its spectrum is

\[ f(\omega) = \gamma_0 = \sigma^2, \]  

a constant for all value of frequency \( \omega \). That is, the plot of the spectrum of white noise is flat against \( \omega \). The spectrum of white noise can be estimated through the periodogram of finite observations with length \( n \). Let \( g_k \) be the sample autocovariance computed from the \( n \) observations of a stationary time series \( \{ Y_t \} \):

\[ g_k = \frac{1}{n-k} \sum_{t=k+1}^{n} (y_t - \bar{y})(y_{t-k} - \bar{y})/n, \]  

where \( \bar{y} = \frac{1}{n} \sum_{t=1}^{n} y_t \). Then, the periodogram ordinates are

\[ I(\omega) = g_0 + 2 \sum_{k=1}^{n-1} g_k \cos(k\omega). \]  

usually computed at the Fourier frequencies \( \omega_j = 2\pi j/n \).

The plot of the periodogram ordinates gives a visual examination of the underlying spectrum of the process. For a sample of white noise, its \( I(\omega) \) is distributed as \( \sigma^2 X^2_2/2 \), where \( X^2_2 \) is a chi square random variable with 2 degrees of freedom. Note that \( I(\omega) \) is an unbiased estimator of \( f(\omega) \), but not consistent (Priestley 1981). Many techniques were proposed to construct unbiased and consistent estimators of \( f(\omega) \) using functions of \( I(\omega) \), and many tests on white noise can also be constructed via periodogram ordinates \( I(\omega) \) (Priestley 1981).

White noise is not only the driving force for classic ARIMA models, it also plays a fundamental role in the popular Generalized Autoregressive and Conditional Heteroscedastic (GARCH) models in financial analysis, in vector cointegration models for economic time series, and in long memory time series models such as in Autoregressive Fractional Integrated Moving Average (ARFIMA\((p,d,q)\)) models with \( d \) being a non-integer. White noise is the core of statistical analysis. However, some realizations of simple deterministic chaotic systems may exhibit white noise like sequences. The study of chaos requires new techniques and concepts that are beyond the classic approaches of time series analysis.

BIBLIOGRAPHY

White Primary

Following Reconstruction (1865–1877), white southerners employed various tactics to minimize the economic, political, and social opportunities of former slaves and their descendants. The white primary, which limited blacks’ political influence, was one. A primary is an election within a political party to select the party’s nominees for public offices. Late in the 1800s states began to replace party conventions with primaries as nominating devices. The primary became a “white” primary as participation in it was denied to voters of color. Along with poll taxes and literacy tests, white primaries were “Jim Crow” laws, practices used in the South in the late 1800s and early 1900s to marginalize African Americans politically.

The white primary had significant discriminatory potential because the Democratic Party was virtually the only political institution involved in selecting public officials in the South. The Republican Party had virtually disappeared there; much of its numeric strength was contributed by black voters, whose numbers dwindled in the face of discriminatory voting laws and practices. By denying black voters the option of participating in Democratic Party nominations, they were left with few avenues for effective electoral involvement.

The creation of white primaries could be accomplished in several ways. First, the state could statutorily exclude African American voters from primaries. Alternatively, the Democratic Party itself could adopt rules that either denied the opportunity of party membership to black voters or prohibited black voters from casting ballots in primaries. White primaries could also be effectively created by using other discriminatory practices to disqualify black citizens from involvement in elections.

The black electorate was substantially reduced during this period by requiring prospective voters to pass literacy tests, pay poll taxes, and the like. Because most southern blacks had a rudimentary education at best and because of

Dejian Lai
the pervasive impoverished circumstances in which they lived, these policies were potent barriers to voting by black citizens. It was not particularly necessary to reinforce these devices with statutory white primaries. Moreover, some recognized that the Fourteenth and Fifteenth Amendments to the U.S. Constitution might prevent enforcement of laws that overtly denied to African Americans the right to vote.

Nonetheless, additional efforts to exclude black voters from nomination and election processes were desired by Southern whites. The Democratic Party at the county and state levels began to impose rules that prohibited participation of black voters in party affairs. Texas, however, took this further. There, as in some other southern locations, Democratic factions occasionally relied on black votes to gain and retain official power. A San Antonio faction sought to weaken one of its rivals that used that practice by convincing the state legislature to adopt a statute prohibiting black voter participation in primaries. The Texas legislature passed just such a law in 1923. Two years earlier the U.S. Supreme Court had decided *Newberry v. United States* (1921), which sprang from a Michigan election for a U.S. Senate seat. In *Newberry* the Court held that Congress could not regulate campaign spending in congressional primaries because primaries were not elections under Article I, Section 4 of the U.S. Constitution. Texas proponents of a statutory white primary thus reasoned that prohibitions of racial discrimination in the Fourteenth and Fifteenth Amendments would not apply to their primaries.

The equal protection clause of the Fourteenth Amendment requires that states offer “equal protection” to all persons in their jurisdictions; it is a prohibition against a state acting in discriminatory fashion. The Fifteenth Amendment simply provides that citizens may not be denied the right to vote on the basis of race, color, or previous status as slaves; it overtly guarantees African Americans the right to vote in elections. The Court’s ruling in *Newberry* evaded these guarantees by holding that primaries were not a part of the electoral process.

Once the Texas statute was in place, a black El Paso doctor, L.A. Nixon, attempted to vote in a Democratic primary and was turned away. He sued Herndon, the election judge who prevented his voting, and claimed that his Fourteenth and Fifteenth Amendment rights had been violated. The U.S. Supreme Court decided *Nixon v. Herndon* in 1927, evaluating its issues solely within the context of the Fourteenth Amendment; the Texas law was held to clearly violate the equal protection clause. No consideration was given to the relevance of the Fifteenth Amendment to the case, nor was the question of whether federal laws applied to party primaries taken up.

Texas responded to the decision by repealing the offending statute and passing a new law permitting a party’s state executive committee to determine the qualifications for political party membership. The Texas Democratic Party then passed a resolution affirming the right of qualified white Democratic voters to participate in the party’s primaries, but no one else. In a subsequent primary Nixon again attempted to vote and was again turned away. He sued once more, and the Supreme Court took up his claim in the case of *Nixon v. Condon* (1932).

The logic of Texas’s new law was that the Fourteenth Amendment specifically prohibited state action that is discriminatory, but the rule barring voting by black citizens was one adopted by the Texas Democratic Party, a private association. Since the rule was made and enforced by a private entity, proponents contended, the Fourteenth Amendment did not apply. The Court, however, disagreed, pointing out that the power to exclude black voters had been given to the party by the state and that the state was using the party to accomplish racial discrimination in voting, thereby violating the equal protection clause.

The Texas legislature then enacted a statute compelling political parties to employ the primary to nominate candidates and giving to parties complete responsibility for the actual conduct of the primary without state direction or supervision. When black voters were prevented from voting under this statute, yet another lawsuit resulted. This time the outcome was different. The Supreme Court ruled in *Grovey v. Townsend* (1935) that since operation of the primary was totally in the hands of a private entity and since political parties could be viewed as “voluntary associations for political action,” a party might exclude African American voters without violating the equal protection clause. In these situations parties were not considered agents or instrumentalities of the state and could determine their own procedures as non-public institutions.

The Court’s ruling in *Townsend* might have ended the debate as to the legal legitimacy of white primaries for some time; however, an unrelated Louisiana lawsuit revived the issue. Primary officials in New Orleans were charged with election fraud in the course of conducting an election for a seat in the U.S. House of Representatives, a violation of federal law. Because there was no competition for the seat in the general election, the primary outcome was tantamount to election. The embattled election officials defended themselves by invoking *Newberry* and asserting that federal law applied only to general elections. In *United States v. Classic* (1941), however, the Supreme Court held that the Constitution created a right to voter participation even in primaries when it gave to “the people in the several states” the authority to select their dele-
gates to the House of Representatives, provided that the primaries are an integral part of electoral procedure. Classic thus reversed the Court’s position in Newberry, but it made no reference to Grovey.

Black voters, though, saw in Classic a stepping-stone to link white primaries to constitutional prohibitions against voter discrimination based upon race. A black Houston dentist, Lonnie E. Smith, had been refused a ballot in the 1940 primary by S. E. Allwright, an election judge. Smith sued and invoked the Court’s finding in Classic, and the Court sided with him and overruled Grovey in so doing. The Court noted the state’s authority to regulate political parties and primaries and concluded that primaries were thus a mechanism for electing public officeholders. Smith v. Allwright (1944) thereby struck down the white primary as an unconstitutional infringement of black voters’ rights.

The impact of white primaries as a delimiter of black voting is not clear, for their specific effects must be disentangled from those of other discriminatory practices and laws. Although it is apparent that African American participation in elections declined during the period white primaries were operated, some analysts assert that literacy tests and poll taxes were principally responsible for the decline in black voting. Similarly, the impact of white primaries’ demise is not obvious; some argue that eliminating the white primary did little to stimulate black voter participation. However, the percentage increase in black voter registration from 1940 to 1947, during which time the white primary was outlawed, is matched only by the increase in black voter registration from 1960 to 1969, when the Voting Rights Act of 1965 was first implemented.

Dismantling the complete array of discriminatory devices was necessary to stimulate widespread African American involvement in politics in the South. If nothing else, litigating the status of primaries in the framework of American elections was essential to making their public role apparent not only to the legal community and to political elites but also to private citizens. Given the almost universal adoption of primaries as nomination devices across the nation, these lessons were as important to nonsoutherners as they were to voters in the South.

**WHITE SUPREMACY**

White supremacy—the belief in the superiority of the white race, especially in matters of intelligence and culture—achieved the height of its popularity during the period of European colonial expansion to the Western Hemisphere, Africa, and Asia stretching from the late 1800s to the first half of the twentieth century. White supremacists have based their ideas on a variety of theories and supposedly proven facts; the most prominent of these include the claims of pseudoscientific racist academic research that attempted to correlate inferiority and pathological behavior with categories of racial phenotypes, especially head size in the case of eugenics. White supremacist belief has also been justified by the Biblical Hamitic hypothesis, which viewed blacks as the descendants of Ham who would be cursed for life. There is a direct correlation between the rise of imperialism and colonialism and the expansion of white supremacist ideology justifying the changing international order, which increasingly saw Europeans assuming political control over peoples of darker skin color through military force and ideological means, such as religion and education. It is important to note that the range of those considered “white” expanded considerably in the twentieth century. For example, in the United States, not all ethnic groups with white skin were initially considered white. It was not until well into the

White Supremacy

twentieth century that the Irish and Italians, for example, were considered white. By the end of that century, the United States federal government had also expanded its definition of whites to include Arabs.

Various groups and institutions have used varieties of white supremacist thinking to organize followers socially and politically, often with the purpose of policing racial barriers. This activism has included, but not been limited to, the physical elimination of nonwhite populations (especially through violence), preventing cross-racial marriage, and maintaining racial segregation. The most well known examples of institutionalized white supremacy were “Jim Crow” segregation in the United States, apartheid in southern Africa, and the Nazi German state under Adolph Hitler, which sought a “final solution” through the extermination in gas chambers of millions of Jews and gypsies, and under which various racial medical experiments were carried out.

The academic field of anthropology has been most closely associated with theories of racial difference, including white supremacy. As anthropology developed as a field in Europe and North America in the 1800s, its epistemological foundations actually provided scholarly legitimacy to the practice of categorizing human beings according to race. In the twentieth century it was also the field that amassed the primary evidence to refute white supremacist thinking. Of particular note as regards this latter phase was the work of Franz Boas, whose fieldwork among North American indigenous peoples provided evidence to refute ideas that races and cultures could be placed in hierarchies that ranged from primitive to sophisticated, with the white race at the top.

After World War II (1939–1945), and the carnage caused by Nazi racial ideology, effort was invested by social scientists to refute white supremacist ideology. Of particular note was the “Statement by Experts on Problems of Race” that the then new United Nations sponsored and had published in the early 1950s. The list of scholars who supported the document comprised the most prominent thinkers on issues related to race at the time, including E. Franklin Frazier, Claude Levi-Strauss, Julian S. Huxley, Gunnar Myrdal, Joseph Needham, and Theodosius Dobzhansky. The central point of the Statement was that race was not based on biological difference and was actually a social construction because all the supposedly different human races belonged to the same species of Homo sapiens.

Due to publications such as the Statement and the mapping of the human genome (which provided additional evidence that there are few significant genetic differences between races), biological justifications for white supremacy popular during the first half of the twentieth century declined in prevalence in the second half. Similarly, by the end of the century all states that had officially declared themselves to be white supremacist had been eliminated. However, white supremacist ideology was resuscitated by a number of social transformations that were particularly evident by the last decade of the twentieth century. These included the end of Communist states in eastern Europe, increased immigration to Europe and North America by nonwhite groups, and the growth of technologies to facilitate rapid transnational communication. White supremacy was deployed by various groups as an organizing tool. In eastern Europe, groups in the former Communist societies used it to create new identities in the wake of communism’s demise, and eastern Europe quickly became the center of neo-Nazi activism. In the United States, groups such as the World Church of the Creator and so-called citizen militias invoked religious and nationalist mythology to rally their believers against the increased power of racialized groups and the presence of illegal immigrants from Latin America. The expansion of the Internet was useful to these hate groups because it facilitated the exchange of documents and enabled the organization of adherents over vast distances. It also allowed some European white supremacy activists to obviate European antiracist propaganda laws that had been enacted after World War II.

The persistence of white privilege, even in societies where nonwhites are the majority, has meant that white supremacy and its consequences have not ceased to be sources of social scientific research. A notable event in the growth of “white studies” was the conference “The Making and Unmaking of Whiteness,” held at the University of California, Berkeley in April 1997. This yielded, four years later, a volume of the same name published by Duke University Press.

In the United States the legal scholar Cheryl Harris, the historian David Roediger, and the American Studies scholar George Lipsitz are among those whose work in white studies has been influential. Melissa Steyn, the South African, has also been a prominent thinker in the area.

White studies is best contextualized as another stage in the evolution of humanities and social science research on the functioning of social systems. One of the most prominent themes in the study of whiteness is identity formation. The argument for doing white studies, and putting it on par with other more established areas of ethnic studies such as black studies, is that the adoption of white identity and the related ideology of white supremacy confer privilege at the expense of others who cannot or will not invest in them.

WHITENESS

Whiteness refers to the nature and social impact of white racial identity. “White” is best understood as a position in a racialized social structure; that is, it is a label that is meaningless outside of a social system where racial categories influence access to social, political, and economic resources and in the absence of other socially constructed identities such as “black” or “Asian.”

Historically, the subject of whiteness was overlooked by mainstream social science in favor of an emphasis upon the “problems” of immigrants and minorities. When whiteness was taken into consideration, it was not as the focus of study, but as the mainstream or baseline against which other groups were compared. One significant exception to this line of thought was presented in African American sources such as the works of W. E. B. Du Bois and those compiled by the editors of Ebony magazine (1966) and David Roediger (1998). That this literature was overlooked is perhaps best understood as a reflection of the historical marginalization of the contribution of African American writers to the study of race relations.

Whiteness studies emerged in the late 1980s and early 1990s in such fields as history, sociology, critical legal studies, cultural studies, anthropology, and education. In sharp contrast to earlier work in the field of race and ethnic relations, whiteness studies involves an explicit focus upon the socially constructed nature of white racial identity and the role of whiteness in the reproduction of racism and racial inequality. This serves to emphasize that whites are an important racial collectivity and that it is important to understand how whites perform as racial actors (see Lewis 2004). Seminal early works included Roediger’s The Wages of Whiteness (1991), Ruth Frankenberg’s White Women, Race Matters (1993), and Peggy McIntosh’s “White Privilege” (1988); these works were the vanguard of a large body of literature that flourished after 1995. Why whiteness studies emerged when it did is best explained by a combination of factors, including the continuing challenge to white supremacy in the post–Civil Rights era, the changing racial demography of the United States, the decline of white ethnic identities, and intellectual trends that emphasized the social construction of race and the examination of identities.

MAJOR CONTRIBUTIONS

Major ideas and concepts that emerged from the field of whiteness studies are (1) the importance of white racial invisibility and white privilege, (2) the social and political impact of whiteness, and (3) the historical evolution of whiteness. White racial invisibility is the observation that for most white Americans under most circumstances, white racial identity has little or no social meaning. This “hidden” nature of whiteness is closely connected to the fact that white understandings and practices have historically constituted the social and cultural mainstream of American society. In essence, to be white is to be not different, to be “just like everyone else.” White invisibility is also linked by many writers to white privilege, the unearned and invisible benefits (e.g., being viewed as an individual) that whites experience in everyday life (McIntosh [1988] 2002).

A second core insight of whiteness studies has emphasized the effect of white invisibility on racial politics and the reproduction of racial inequality. The hidden nature of whiteness has made it more difficult for many whites to understand the experiences of racial minorities and the persistence of racial inequality. This has led to the emergence of what many writers have termed color-blind racial ideology (see Bonilla-Silva 2001), the claim that racism is a thing of the past and that race no longer matters in American society. From the color-blind perspective, racial inequality is due to the failure of individuals to take advantage of opportunities for mobility. Carried to an extreme, it even leads to the claim that white Americans experience significant race-based economic and cultural victimization (see McKinsey 2005).

The social and political effects of whiteness have also been studied at the institutional level. As Cheryl Harris observed in “Whiteness as Property” (1993), whiteness can be viewed as “property” in that it has historically embodied social and economic benefits for whites. The historian Ira Katznelson, in When Affirmative Action Was White (2005), chronicled how New Deal and other mid-twentieth-century programs widened the economic gap between white Americans and peoples of color. Other writers have highlighted how the government’s urban, housing, and fiscal policies have resulted in the systematic and unequal accumulation of wealth by white Americans.

A third focus of whiteness studies has been on the evolution of whiteness. Much of this analysis has been historical, as scholars such as David Roediger (2005), Noel

BIBLIOGRAPHY

Ignatiev (1995), and Matthew Frye Jacobson (1998) have traced how immigrants from Ireland and southern and eastern Europe initially faced both discrimination and an uncertain racial status but later “became” white and were absorbed into the dominant racial group. This argument is not universally accepted, as other writers (e.g., Guglielmo 2003) have asserted that groups such as Italians were “white on arrival,” and that their whiteness made it easier to be accepted into American society. What is less contentious is that European immigrants learned what it meant to be white in the United States, especially with respect to establishing themselves in contrast to African Americans.

Another element of the evolution of whiteness has involved the construction and reconfiguration of racial boundaries and the meaning of whiteness. As Ian Haney López has documented in White by Law (1996), the question of who was (and who was not) white was socially contested and was frequently adjudicated by the courts. With the passage of time, white ethnic identities and intragroup boundaries have dissipated, leading to the emergence of a more generic white, European American identity (see Doane 1997). Future changes may continue to redefine whiteness. As Eduardo Bonilla-Silva asserted, social and demographic forces may lead to the expansion of “white” identity to include some Latino and Asian American groups, as well as persons claiming a multiracial identity (2003).

CRITIQUE AND FUTURE DIRECTIONS

While relatively new, whiteness studies is not without its critics. One charge leveled at whiteness studies, and at the study of racial groups and categories in general, is that the attention paid to whiteness tends to essentialize it as an objective and omnipotent social force. Whiteness studies has frequently been guilty of viewing whites as a homogenous, monolithic social entity where certain qualities are ascribed to all whites. Clearly, while whiteness involves a shared social context that influences individual and group behavior, there are significant intragroup differences that determine how whiteness is perceived and experienced (see, for example, Hartigan 1999). In addition, as Margaret Andersen observed in “Whitewashing Race” (2003), authors writing on whiteness have tended to emphasize white identity and privilege while deflecting attention from key issues of power, inequality, and racism.

Whiteness studies faces many challenges in the future. Clearly, whiteness cannot be understood in isolation—apart from racism and racial inequality. It is also essential to study the complexity of whiteness; that is, to explore how variations in factors such as class and situation produce differences in the social role of whiteness. Equally important is the need to keep abreast of changes in the nature and expression of whiteness. Past studies have highlighted moments when whites, both individually and collectively, became racially self-conscious actors, especially as a defense in the face of perceived challenges or threats from other groups (e.g., anti–Civil Rights movement backlash, various anti-immigrant movements). As U.S. society and its institutions become more diverse, the social and political meaning of whiteness will continue to evolve. If the field of whiteness studies is to make a meaningful contribution to understanding race and ethnic relations, then it must successfully confront these issues.

WHITENING

From the 1400s to the 1900s European colonialism and imperialism exported an ideology of white superiority throughout the world, rationalizing European ascendance over indigenous, inferior-raced peoples fit for conquest, exploitation, and domination. From this history a white-dominated sociopolitical order has been constituted, normalized, and maintained. As a result whiteness and the process of “whitening” have emerged as both ideal and practice. Significantly whiteness as an ideal communicates ideas about superiority with respect to moral or intellectual and aesthetic worth. Although conceptually distinct, there is a psychological tendency to conflate the two, and attempts at whitening, by both individuals and nations, have sought to capitalize on a supposed white superiority in both respects.

WHITENING AS AN INDIVIDUAL IDEAL

The elevation of whiteness both justifies the material and psychological privileging of whiteness and reinforces the white ideal. Unsurprisingly this has encouraged individuals to adopt a variety of strategies aimed at whitening physical appearance. Skin lightening is a prominent example, and the United States is instructive in examining how this strategy emerged historically.

The institution of U.S. slavery was undergirded by powerful rules maintaining racial differentiation, including those regarding hypodescent. According to the “one-drop rule,” individuals with any ascertainable “Negro blood” were considered black, a determination that served slaveholders’ property interests in slaves while reinforcing the ideological fiction of white purity and superiority. Slaveholders also instigated tension between lighter- and darker-skinned blacks through colorism, differentiating among blacks to prevent their alliance in potential revolts. Lighter-skinned slaves were often “privileged” as house servants relative to darker “field” slaves, for example, receiving less-violent treatment and greater opportunities for education, skilled labor, and even manumission.

In this extreme racialized context, enslaved African Americans began applying lye and other harsh cleaning products to lighten their skin. Other household concoctions included applying lemon juice, bleach, and even urine to the skin and swallowing arsenic wafers. Advancements in modern medicine encouraged more scientifically “legitimate” methods, researched and developed by the medical community. Whitening products began appearing during the nineteenth century, and by the early twentieth century hundreds of unique brands were available.

In the early twenty-first century skin whitening is a global, multibillion-dollar industry that includes major cosmetics corporations, including L’Oreal, Maybelline New York, and Lancôme Paris. L’Oreal alone made $14 billion on skin whitening products in 2003. In the United States and elsewhere, consumers of whitening products include not only blacks but also other people of color and darker-complexioned whites. Typical products include soaps, creams, and ointments that often contain mercury, topical corticosteroids, or hydroquinone, each of which disrupts melanin production in the skin. Although touted as safe by regulators, side effects of such products range from permanent spots and splotchiness to disfigurement and even poisoning. Indeed whitening products are often made in third world countries, imported legally and illegally, and sold on Internet domains to avoid regulations and critical resistance.

Reinforced by popular media and persistent disparate treatment, marketing of the white beauty ideal extends beyond skin whitening to include hair straightening, hair weaving, and colored contact lenses. Increasingly popular are more permanent and medically intrusive procedures, such as plastic surgery. Consider, for example, the use of rhinoplasty among black and Jewish Americans and the growing prevalence of eyelid surgery among Asian Americans. Even strategies such as marrying “lighter” and distancing oneself from dark-skinned people and communities, both literally and through self-classification, are considered forms of whitening by some scholars.

Ashley (“Woody”) Doane
WHITENING AS A NATIONAL PRACTICE

Significantly the whiteness ideal has not only influenced individuals but has also become the basis of large-scale state policies seeking to whiten national populations. Many Latin American countries in particular—including Brazil, Venezuela, Cuba, Argentina, Uruguay, and Colombia—enacted collective whitening strategies during the nineteenth and twentieth centuries. Such efforts typically revolved around promoting white European immigration (often while restricting immigrants of color) and encouraging “race mixing,” or miscegenation, as a way of gradually lightening the total population. Brazil offers one of the best-examined cases of a whitening ideology influencing national goals.

Portugal colonized Brazil beginning in the sixteenth century, dominating the indigenous population and instituting the importation of 3.6 million enslaved Africans over three centuries. Brazil’s racial composition was dramatically altered both directly via slavery and via the mixed-race children born of frequent unions (often violent and coerced) between Portuguese colonizers and African and indigenous women. By the end of the eighteenth century blacks and their descendants formed a majority of the Brazilian population.

Brazil’s largely mixed-race population was problematized in the nineteenth century, as Europe’s burgeoning racism reached the nation. Such theories validated the white political and economic domination characteristic of colonial nations by asserting the superiority of the white race, associated with progress and advancement, while deeming other, darker races as inferior and backward. The views of Count Arthur de Gobineau of France were exemplary of such thinking. For Gobineau, Brazil epitomized the perils of miscegenation, which in his view had produced a degenerate people, dooming the country to perpetual underdevelopment.

As a way out of such fatalistic predictions, Brazil turned to the project of whitening, or blanqueamiento, as a national solution. Brazilian eugenicists proposed a theory of “constructive miscegenation” based on the belief that white genes were stronger and would “dominate” and “purify” colored blood. Miscegenation was rearticulated as an assurance that Brazil could achieve a whitened population over several generations and the inferior features of African and indigenous ancestry overcome. To further hasten the process of national whitening, Brazil encouraged, recruited, and subsidized European immigration to fill postslavery labor needs while simultaneously prohibiting black (both African and American) and Asian immigration. The Brazilian government attempted to lure European immigrants, both directly and through landowners, by paying transportation costs, exempting tax payments and military service, and offering loans, grants, and other material incentives. European immigration promised to whiten the population both by literally increasing the number of whites in the country and through ensuing miscegenation.

While Brazil’s first census in 1872 documented 37 percent of the population as white, by the 1890s more than 1.2 million Europeans had immigrated, bolstering the percentage to 44 percent. Mass European immigration halted with the onset of World War II, but by 1940 fully 64 percent of Brazil’s population was white. From 1940 onward the brown, mixed-race population increased, while the black population steadily declined.

Of Latin American nations, Argentina was perhaps the most “successful” with respect to whitening, virtually eliminating the Afro-descendant racial group. Colombia offers a unique comparison. When European immigration proved unattainable, elites sought the next best thing—interregional migration as a means of whitening. For example, elites from the Colombian region of Cauca encouraged the migration of neighboring Antioqueños, emphasizing their European- and “Yankee-like” qualities and appearance.

Predominantly white countries, while not instituting explicit whitening policies, have attempted to maintain the national dominance of whiteness. For instance, the United States, Canada, and Australia all maintained discriminatory immigration policies, privileging white European immigrants and limiting or excluding immigrants of color until the late twentieth century. Historically the United States engaged in other legal efforts to firmly differentiate between whites and people of color, particularly blacks, including codifying racial designations through rules of hypodescent, limiting nonwhite citizenship, barring miscegenation, and enacting legalized segregation. Additionally, although some early immigrants, including the Irish and Italians, were originally discriminated against as nonwhite “races,” white elites eventually extended what has come to be known as the “wage of whiteness” to such groups in an effort to manage changing demographics and diminish the likelihood of cross-racial coalitions. Clearly practices such as these serve to entrench the racial structure that privileges whiteness both nationally and globally.

In the early twenty-first century the ideology of white superiority persists, although its expression may be less explicit. Nonetheless, as long as whiteness is maintained as a privileged status, materially and psychologically, whitening, as both ideal and practice, will also persist.

WHITES

The issue of whiteness is intimately tied to the issue of social construction. Whiteness is a social construction that serves to empower some and disenfranchise others. The fact of the social construction is often masked as a referent to biological categories. As Grace Elizabeth Hale points out, “Long before they [whites] conceived of regional differences, early Americans linked skin color to the origins of peoples, using it to distinguish various nationalities and ethnicities of African, Native Americans, and Europeans” (Hale 1998, p. 4). David Roediger suggests that “the term white arose as a designation for European explorers, traders, and settlers who came into contact with Africans and the indigenous people of the Americas” (Roediger 1991, p. 21). The early uses of the term white were to distinguish Native Americans and Africans from Europeans.

According to Karyn McKinney, “Before it became popular to write of the ‘social constructions of whiteness,’ African American scholars, such as W. E. B. DuBois, James Baldwin, and Ralph Ellison had recognized race as a social rather than biological trait, and the fact that one ‘becomes,’ rather than is born, white.” Ellison and other black scholars also highlighted the observation that the quickest way for an immigrant to “become” white, and thus feel “instantly American,” was to learn to deride African Americans (McKinney 2005, p. 11).

The historical boundaries of whiteness continue to change over time. As Matthew Frye Jacobson (1998) has noted, the historical construction of whiteness was tied to the political notion of “fitness for government,” and the process of defining who was or was not white occurred largely as a result of legal decisions in the determination of citizenship (Haney-López 1996). Furthermore, Joe Feagin, Hernán Vera, and Pinar Batur suggest:

Those called “whites” in the United States and across the globe are really not white in skin color but rather are some shade of brown, tan, pink, or mixture thereof. These truer-to-life skin colors, however, are not generally associated with the qualities—such as purity, innocence, and privilege—to which “white” skin is often linked. White people do not exist in the flesh; they are a social construction. (Feagin et al. 2001, p. 2)

THE WAGE OF WHITENESS

W. E. B. Du Bois (1868–1963) considered the economic aspects of embracing the ideology of whiteness. He brilliantly developed a concept for analyzing class—the psychological wages of whiteness. This concept spearheaded contemporary scholarship on the process of immigrants embracing the category of white in America. The psychological wage of whiteness meant that:
The white group of laborers, while they received a low wage, was compensated in part by a sort of public and psychological wage. They were given public deference and titles of courtesy because they were white. They were admitted freely with all classes of white people to public functions, public parks, and the best schools. The police were drawn from their ranks and the courts, dependent on their votes, treated them with leniency as to encourage lawlessness. Their vote selected public officials, and while this had small effect upon the economic situation, it had great effect upon their personal treatment and the deference shown them (DuBois [1935] 1969, pp. 700–701).

As Noel Ignatiev suggests:

The hallmark of racial oppression [is the reduction of] all members of the oppressed group to one undifferentiated social status, a status beneath that of any member of any social class within the dominant group…. It follows, therefore, that the white race consists of those who partake of the privileges of the white skin in this society. Its most wretched members share a status higher, in certain respects, than that of the most exalted persons excluded from it. (Ignatiev 1995, p. 1)

McKinney further notes that “in the United States whiteness is so central a social reality, so ‘normal,’ that most whites of all ages rarely examine the reality of their white identities and privileges. For most whites, including scholars and commentators, even the term ‘American’ seems to conjure up the image of a white person” (McKinney 2005, p. xii).

HOW THE IRISH AND JEWS BECAME WHITE

The Irish became white, according to Ignatiev, when they immigrated to America “in the eighteenth and nineteenth centuries [because] they were fleeing caste oppression and a system of landlordism that made the material conditions of the Irish peasant comparable to those of an American slave” (Ignatiev 1995, p. 2). The Irish, upon arrival, found themselves thrown into the neighborhoods, status, and categorization of African Americans. They quickly discovered the importance of skin color and adopted the ideology of a racial hierarchy that was pervasive in America. The Irish made a conscious choice to enter the white race.

To the Irish, embracing the country’s racial ideologies offered the benefit of a degree of privilege and citizenship that was not provided to African Americans. Becoming white meant that they were not restricted to working and selling their goods in segregated areas. “It meant that they were citizens of a democratic republic and they could vote, live where they wanted to live, and spend without racially imposed restrictions. In becoming white the Irish ceased to be Green” (Ignatiev 1995, p. 3).

The Irish did not just become white because they wanted to be white; Brodkin suggests that they were assisted and supported by Jacksonian Democrats and the white elite. The willingness of the Irish to participate in organized racial violence against African Americans also contributed to their being accepted into the white racial hierarchy (Brodkin 1998, p. 65). According to Roediger, the Irish worker embraced white supremacy and thus gained popularity in America: “The success of the Irish in being recognized as white resulted largely from the political power of Irish and other immigrant voters” (Roediger 1991, p. 137).

The techniques utilized by the Irish to become white resemble the ways in which American Jews became white. For the Jews, becoming white was based on the assistance of the federal government and their willingness to embrace the white racial hierarchy and ideology. According to Brodkin, who is Jewish, all the members of her family had to learn the ways of whiteness through years of socializing with whites. “The myth that Jews pulled themselves up by their own bootstraps ignores the fact that it took federal programs to create the conditions whereby the abilities of Jews and other European immigrants could be recognized and rewarded rather than denigrated and denied” (Brodkin 1998, p. 50). Jews embraced the country’s racial hierarchy, and they received aid from federal programs set in place after World War II (1939–1945). Many of the programs were designed to discriminate against African Americans who had served in the war. Jews became white and enjoyed the benefits of federal programs such as the GI Bill, the Federal Housing Administration, and the Veterans Administration. These programs overlooked and denied benefits to African Americans. And like other white ethnic groups had done in the past, to prove their commitment to embracing their white status, Jews engaged in racial violence that targeted African Americans and other people of color.

CRITIQUING “WHITE”NESS

Brodkin and Ignatiev attribute becoming white to acquiring political, social, and economic acceptance, as well as assimilating into the American lifestyle. However, Eduardo Bonilla-Silva points out, “When race emerged in human history, it formed a social structure (a racialized social system) that awarded systemic privileges to Europeans (the peoples who became ‘white’)…. Since actors racialized as ‘white’—or as members of the dominant race—receive material benefits from the racial order, they struggle (or passively receive the manifold wages of whiteness) to maintain their privileges” (Bonilla-Silva 2003, p. 9). Those who
have become white, such as the Irish, Jews, and some white Latinos, go on to embrace the white racial hierarchy and ideology of the dominant society.

Joe Feagin similarly points out:

In its use for human groups, the word “white” was originally defined by the English colonist mainly in contrast with “black”…. White defined who the European Americans were, and who they were not. Whiteness was indeed a major and terrible invention, one that solidified white thinking into an extensive and racialized either/or framework and that came to symbolize for whites the “ownership of the earth” and “civilization.” (Feagin 2006, pp. 14–15)

“Moreover,” according to Feagin, “whites are collectively so powerful that they pressure all new immigrants groups, including immigrants of color, to collude in the whiteness system by adopting not only general white ways of doing and speaking … but also the white racial frame and its view of the racial hierarchy of U.S. society” (Feagin 2006, p. 292). New immigrants who come into the United States strive to speak, dress, and act white based upon the white racial hierarchy that decides who is white and who is nonwhite. Furthermore, buying into the cultural attributes of whiteness includes internalizing and supporting antiblack sentiment.

Chris Cuomo and Kim Hall suggest that because of the role of whiteness “in justifying and maintaining racism and colonialism in the United States (and, now, most of the world), whiteness is uniquely located on the racial map. For whites to fail to consider whiteness as a historical, constructed, and dynamic category is to risk treating it as normal (rather than normalizing), uniform (not immeasurably variable), paradigmatic (instead of fundamental to racism), and given (rather than dutifully maintained)” (Cuomo and Hall 1999, p. 3). In the early years of the twenty-first century, the historical techniques of becoming white are being adopted by new Latino immigrants who, for the purpose of reaping the benefits of whiteness, classify themselves as white.

WHOLESALE PRICE INDEX

The Wholesale Price Index (WPI) measures average price changes over time in the stage prior to the final demand, covering therefore the flow of goods and services from the wholesaler to the retailer. Available on a daily, weekly, monthly, or quarterly basis, this index supplies information constructed from the point of view of gross transactions at the purchaser’s prices, information that is useful to understand, anticipate, or coordinate the economic activity, particularly in large-scale industrial economies. Because there is a short interval between the inquiries and the public release of the indexes (the norm being divulga two weeks after the end of the month or the quarter), the information provided by the synthesis-numbers allows producers, traders, and government officials to gauge, at a glance, the current tendencies of economic evolution. This practical and utilitarian nature is further reinforced by the fact that the Wholesale Price Index captures price movements in advance to the retail level, and is likely to foreshadow subsequent changes in the price of goods and services purchased by consumers. In vertical, integrated markets this time advance tends to be shorter in circumstances of price increases and longer in price decreases.

Historically, the revolution in transportation and communications of the late nineteenth century paved the way for the appearance of this kind of aggregate measure-
ment of prices. The connection between the network of enterprises and businessmen working out in distant regions became reinforced through the public diffusion of economic statistics such as prices composites, aggregate index of commodities, and wholesale price indices published by several U.S. newspapers. At the beginning of the twentieth century important nongovernmental institutions also set up solid reputations in the release of weekly and daily series of index numbers. The first official initiatives came out almost simultaneously in the United States (1902) and in Europe (United Kingdom, 1903), in response to parliamentary investigations into the effects of laws and tariffs on domestic prices. Japan saw the establishment of a Wholesale Price Index of Tokyo City in 1897, through the initiative of the Bank of Japan.

A major drawback of these pioneer undertakings was the proliferation of methods for computing the average price of the commodities, and also the limited coverage given by price quotations. The introduction of a system of weighting, combined with an enlarged sample of goods taken from widely distributed markets, under the responsibility of the United States Bureau of Labor Statistics in 1914 marked a new phase in the credibility of governmental agencies. Up to the present time, the formula that closely approximates the computation procedures in use around the world for weighting the “basket of commodities” comprised in the Wholesale Price Index is some variant of the index formula suggested by Etienne Laspeyres in 1871. Thanks to these developments, the scope of the Wholesale Price Index is some variable in relative prices corresponding to a change in income distribution, given the system of production in use. A WRE in addition takes into account the problem of the choice of technique. The “changes” under consideration refer to comparisons of long-period equilibria.

Knut Wicksell (1954; 1934, pp. 147–151) discussed these effects within an “Austrian” framework of the analysis, which conceives of production as a one-way avenue of finite length leading from the services of original factors of production, in particular labor, via some intermediate products to consumption goods. Before Wicksell they had been studied by the classical economists, especially David Ricardo (Works I, pp. 30–43), who wrote that relative prices depend on income distribution because of the “variety of circumstances under which commodities are actually produced” (Works IV, p. 368). This in conjunction with the fact that “profits [are] increasing at a compound rate … makes a great part of the difficulty” (Works IX, p. 387). Ricardo also tackled the problem of the dependence of the chosen technique on distribution in his disquisitions on rent and on machinery (1951–1973). The classical economists and Karl Marx typically conceived of production as a circular flow where commodities are produced by means of commodities.

The source of PWEs can be illustrated by expressing the ratio of the prices of two commodities, \( A \) and \( B \), by means of their “reduction to dated quantities of labour” (Sraffa 1960, chapter VI). Call \( p_a \) and \( p_b \) the prices of one unit each of two commodities, \( w \) the wage rate per unit of labor (paid post factum), and \( r \) the rate of interest (or profits). Then we have

\[
\frac{p_a}{p_b} = \frac{w_{a0} + (1+r)w_{a1}}{w_{b0} + (1+r)w_{b1}} + (1+r)^2w_{a2} + \ldots + (1+r)^{n}w_{an} + \ldots
\]

(On the RHS of the equation \( w \) could be eliminated.) Obviously, \( l_{a0} \) \((l_{b0})\) gives the amount of labor expended directly on the last stage of producing one unit of commodity \( a \) \((b)\); \( l_{a1} \) \((l_{b1})\) the amount expended directly on the last but one stage; and so on. Whereas with the Austrian concept each series is finite, with the classical circular flow concept it is infinite. Because for a given system of production the rate of interest and wages are inversely related (as has already been established, albeit imperfectly, at the
time of the classical economists), a change in distribution typically affects the prices of the two commodities differently: It all depends on how the total amounts of labor expended are distributed over time—whether or not relatively much labor is expended in early periods of time and little in later ones. Because with a rise of $w$ and the corresponding fall of $r$ the size of each term in each of the reduction equations (except the first one) is pulled in different directions, the overall effect of a change in distribution on relative prices depends on how the time patterns of the labor inputs compare with one another, with compound interest as a magnifier.

With a choice of technique, a change in the real wage rate may prompt cost-minimizing producers to change the methods of production to produce the various commodities. This brings us to the concept of RWE. In order to be able to compare the new situation with the original one, it has to be assumed that in both situations the same net output is produced; typically the economy is taken to be in a stationary state both before and after the change. The questions to be answered are: (1) which technique will be chosen in the new situation? (2) what will then be the level of the other distributive variable and the set of normal prices? and, most importantly, (3) is it possible to say anything definite about how the two situations compare with one another?

To illustrate RWEs, we may refer back to the equation above, but now $A$ and $B$ stand for two different processes of production of a given commodity available to producers. In competitive conditions the method chosen will be the one that allows one to produce the commodity at lower unit costs and thus a lower price.

Marginalist theory, of which Austrian theory is but a variant, maintains that both effects are positive. A positive PWE means that with a rise (fall) in the rate of interest, consumption goods will become relatively more (less) expensive compared with capital goods. The reason given is that consumption goods are said to be produced more capital intensively than are capital goods, because consumption goods emerge at the end of the production process, whereas capital goods are intermediate products that gradually “mature” towards the final product. The higher (lower) the rate of interest, the less (more) expensive the intermediate products in terms of a standard consisting of a (basket of) consumption good(s). At the macro level of a stationary economy (in which the net product contains only consumption goods), this implies that with a rise in the rate of interest, the value of the net social product rises relatively to the value of the aggregate of capital goods employed. Clearly, seen from the marginalist perspective, a positive PWE with regard to the relative price of the two aggregates under consideration involves a negative relationship between the aggregate capital-to-net output ratio on the one hand and the interest rate on the other. Let $K/Y = x_p(r)/y_p(r)$ designate the capital-output ratio, where $x$ is the row vector of capital goods, $y$ the row vector of net outputs, and $p(r)$ the column vector of prices (in terms of the consumption vector) which depends on $r$; then the marginalist message is:

$$\frac{\partial (K/Y)}{\partial r} \leq 0 \quad (I)$$

Because for a given system of production the amount of labor is constant irrespective of the level of the rate of interest, the ratio of the value of the capital goods and the amount of labor employed, or capital-labor ratio, $K/L$, would also tend to fall (rise) with a rise (fall) in the rate of interest:

$$\frac{\partial (K/Y)}{\partial r} \leq 0 \quad (II)$$

This is the first claim marginalist authors put forward. The second is that RWEs are also positive. A positive RWE means that with a rise (fall) in the rate of interest, cost-minimizing producers switch to methods of production that generally exhibit higher (lower) labor intensities, “substituting” for the “factor of production” that has become more expensive—“capital” (labor)—the one that has become less expensive—labor (“capital”). Hence (II) is said to apply also in this case. The assumed positivity of the RWE underlies the marginalist concept of a demand function for labor (capital) that is inversely related to the real wage rate (rate of interest).

Careful scrutiny of the marginalist argument has shown that it cannot be sustained generally: There is no presumption that PWEs and RWEs are invariably positive. In fact, there is no presumption that techniques can be ordered monotonically with the rate of interest (Sraffa 1960). As Mas-Colell (1989) stressed, the relationship between $K/L$ and $r$ can have almost any shape. The finding that PWEs and RWEs need not be positive challenges the received doctrine of the working of the economic system as it is portrayed by conventional economic theory with its reference to the “forces” of demand and supply.

Widow’s Cruse

Heinz D. Kurz

WIDOW’S CRUSE

The term *widow’s cruse* was first used in economics by John Maynard Keynes (1930, p. 139) in the presentation of his fundamental equations. Keynes argued that enterprise macroeconomic profits, as he defined them there, or what we would now call “business retained earnings,” moved up one-to-one with increases in investment and increases in consumption out of profits. Thus, Keynes argued that “however much of their profits entrepreneurs spend on consumption, the increment of wealth belonging to entrepreneurs remains the same as before. Thus profits, as a source of capital increment for entrepreneurs, are a widow’s cruse which remains undepleted however much of them may be devoted to riotous living” (p. 139). Keynes was then making a reference to the Old Testament story (1 Kings 17) in which a widow was assured that her barrel of meat and jar of oil would never be depleted.

The analogy was later picked up by Nicholas Kaldor (1956), when he presented his Keynesian theory of income distribution and growth. Both Keynes (1930) and Kaldor (1956) assumed full employment. For both of them, lower propensities to save would lead to an increase in prices relative to costs, and this would entail higher profits in the static case of Keynes and higher profit share and profit rates in the dynamic case of Kaldor.

In the meantime, another version of the widow’s cruse was put forward by Michał Kalecki (1942), without the full-employment assumption, based on adjustments through quantities (real output and employment) rather than prices. Kalecki’s equation reads that \[ \text{Profits} = \text{Investment} + \text{Consumption Out of Profits}, \] under the classical assumption that wages are all spent. Taking the public sector into account, government deficit should be added to the right-hand side. Kalecki’s equation has given rise to the aphorism—attributed to Kalecki, but which can be found in Kaldor (1956, p. 96)—that “capitalists earn what they spend, and workers spend what they earn.” This aphorism shows the asymmetry in capitalist relations: Capitalists can always decide to spend more (provided banks accept to finance additional investment), whereas workers cannot decide to earn more, because this depends on the employment they are offered by entrepreneurs. Modern versions of this quantity-adjusting theory can be found in the so-called Kaleckian models of growth, which show that a decrease in the propensity to save leads to higher rates of output growth and higher rates of profit.

The widow’s cruse is the price-adjusting equivalent of the quantity-adjusting paradox of thrift. With output adjusting through the multiplier, the short-run version of the paradox of thrift asserts that individual efforts to increase saving will be useless, and that, instead, output will fall, as was outlined by Keynes in 1936. But this is simply the quantity analogue of the mechanisms he was describing in 1930 as the “Danaid jar,” which can never be filled up, or the “banana parable,” whereby a thrift campaign in a banana-producing economy will lead only to rotten bananas, heavy business losses, large unpaid bank loans, and destroyed wealth.

The widow’s cruse is just as relevant now as it was at the eve of the Great Depression. Mainstream economists and right-wing think tanks are still chanting the virtues of household savings and government budget surpluses, without realizing that household expenditures have sustained the U.S. economic boom and that government deficits add to business profits. The issue of public pension-funds finance is also related to the widow’s cruse, which implies that such funds can only be financed as a pay-as-you-go redistribution mechanism: If one attempts to save too much, the savings will vanish like the rotten bananas.

Widow’s Cruse

96 INTERNATIONAL ENCYCLOPEDIA OF THE SOCIAL SCIENCES, 2ND EDITION
Wilmot Blyden (1832–1912) of Saint Thomas, J. J. Thomas (1840–1889) of Trinidad, J. A. Rogers (c. 1883–1966) of Jamaica, Theophilus A. Marryshow (1887–1958) of Grenada, C. L. R. James (1901–1989) and George Padmore (1903–1959) of Trinidad, and Norman Eustace Cameron (1903–1983) of Guyana were among his precursors and contemporaries. Most of these men had no university training or had studied subjects other than history. When Eric Williams graduated first among the firsts at Oxford University in 1935 and went on to obtain his D.Phil. there in 1938, he ushered in a new era in Anglophone Caribbean historical scholarship.

Williams grew up in Port of Spain, the son of a minor civil servant. He had a distinguished academic record from childhood and won an island scholarship, the ultimate achievement of high school excellence. This entitled him to a free university education, and he broke with tradition by choosing to read history, rather than the law or medicine favored by scholarship winners before and after him. Along the way Williams experienced an unusually eclectic array of influences. C. Augustin Petioni, later a pioneer of Marcus Garvey's (1887–1940) Universal Negro Improvement Association and a leader of the Caribbean independence movement in the United States, was a friend of his father. So was T. A. Marryshow, a pioneer journalist and the “father of West Indian federation.” Williams's brilliance in elementary school brought him the long-standing patronage of Englishman J. O. Cutteridge, arguably the most important figure in the era of colonial education in Trinidad, but a man much disliked in nationalist circles. At Queens Royal College in Port of Spain, C. L. R. James, later one of the outstanding intellectual figures of his generation, was both Williams's teacher and a fellow member of the school's cricket team.

While at Oxford, Williams interacted extensively with James, Padmore, and their coterie of Pan-Africanist (and often Marxist) radicals. He interested himself in the affairs of various nationalist groups, including those of Indian students. As an Afro-Caribbean person in England he inevitably came into contact with racism.

In 1939 Williams began teaching at Howard University, America's most prestigious African American university at the time. Here he interacted with a cast of brilliant scholars, among them Alain Locke (1886–1954), Ralph Bunche (1886–1954), Rayford Logan (1897–1982), and E. Franklin Frazier (1894–1962). Williams distinguished himself even in this distinguished crowd. Two Rosenwald fellowships enabled him to pay research visits to the non-English speaking territories of the Greater Antilles. He won the Journal of Negro History's prize for best article of 1940. His first book, The Negro in the Caribbean, appeared in 1942 in a series edited by Locke. His second, The Economic Future of the Caribbean, coedited with Frazier, was published in 1944. In 1944 his magnum opus, Capitalism and Slavery, was published by the University of North Carolina Press.

**Capitalism and Slavery**, a revised version of Williams's doctoral dissertation, assured him a position of preeminence in Caribbean historiography. It demonstrated in exhaustive detail how the unprecedented profits generated by the slave trade in Africans provided the economic wherewithal for the Industrial Revolution in England. Williams argued that the productive forces unleashed by the Industrial Revolution in turn eventually made slavery itself obsolete. For the new industrial and technological age, slavery had become an outmoded form of production and a brake on development. Slavery was abolished in the British Empire as a result of these economic forces. The abolitionist "saints" of British historiography were not primarily responsible for abolitionism. Theirs was a secondary role, which, happily for them, happened to coincide with the economic necessity of the time. Capitalism and Slavery was hailed as a masterpiece in some quarters and as an unwarranted attack on cherished orthodoxy in others. The battle over this book has never subsided.

Williams's book was doubtless influenced by his very unique attributes. Here was an Afro-Caribbean colonial who had beaten the best that the mother country had to offer, in the most prestigious of English universities. He had also indulged actively in the radical anticolonial activity of the time. He acknowledged C. L. R. James as the source of the thesis that underlay his book. James's *The Black Jacobins* (1938) had posited a similar idea for the French colonial empire, and Williams had helped James work on this book. Williams's years in the United States, while he revised his dissertation, were also a period of constant contact with Caribbean and African American radicals, as well as with such establishment institutions as the Anglo-American Caribbean Commission and the Organization for Strategic Services, a U.S. espionage agency (for both of which Williams worked). Williams was a full-time official for the Anglo-American Caribbean Commission (later the Caribbean Commission) from 1946 to 1955. In this capacity he crisscrossed the Caribbean and researched a huge swath of Caribbean economic and social life. This complemented his already deep knowledge of the area's history. There was probably no one else who could rival his historical and contemporary knowledge of the area.

The excellence of Capitalism and Slavery and Williams's many articles in scholarly journals did not open the door to major publishers. The University of North Carolina Press required him to pay a considerable subsidy, which he was able to raise only after several months of effort. It would be a quarter of a century before another major publisher would do the first printing on any of his
books. Various subsequent publishing proposals came to naught. His manuscript on *Education in the British West Indies* remained unpublished for years until he published it in Trinidad in 1950. Between 1944 and 1969 Williams nevertheless authored or edited nine important works, all published directly or indirectly through his own efforts. Some were published under the auspices of his Historical Society of Trinidad and Tobago. Some were published by the press of the Peoples National Movement (PNM), the political party that took him to political power in Trinidad in 1956. In 1969 André Deutsch published Williams's autobiography, *Inward Hunger*, the first of his books to be initially released by a major publisher in twenty-five years.

Williams wrote history with a passion matched by few professional historians. For him history was a tool of the anticolonial struggle and a stepping stone to politics. His *Historical Society of Trinidad and Tobago* brought history to the masses in the early 1950s. He spread the society’s work with the same energy that had characterized his efforts to promote *Capitalism and Slavery*. (He bought copies from the publishers and resold them himself through a network of friends and helpers). His *Education in the British West Indies* (1950) was a manifesto for a Caribbean university. His *History of the People of Trinidad and Tobago* (1962) was an independence gift to his nation written, in between his political duties, in one month.

The professional Anglophone historians who followed Williams were often ambivalent toward his historical activism. Elsa Gouveia, the doyenne of the first generation of indigenous historians at the University of the West Indies, vitriolically denounced his *British Historians and the West Indies* (1964) for substituting “new shibboleths for old.” Williams envisaged this work as an exposé of the “prejudices of metropolitan historians.”

Williams's last major work, *From Columbus to Castro* (1970), was a survey textbook for university students. He had worked on it for years. It was vintage Williams, with a lively dogmatic style and a heavy bias toward economic history. It reflected his strengths in the colonial period, but was less detailed on the twentieth century.

Williams's many important works do not provide a complete picture of his historical activity. He published voluminously in academic and popular publications, and issued many of his political speeches as pamphlets. The *Caribbean Historical Review*, published under the auspices of his Historical Society of Trinidad and Tobago, released four issues between 1950 and 1954.

**WILMINGTON RIOT OF 1898**

American history is filled with violent racial conflict, oftentimes justified by the perpetrators as necessary to protect (or avenge) honor, life, or property. The Wilmington Riot of 1898 was not an act of spontaneous
violence. Rather, the events of November 10, 1898, were the culmination of a long-range plan by Democratic Party leaders to win control of the city of Wilmington and North Carolina. The party leadership used the concept of white supremacy to regain power lost as a result of a Populist and Republican coalition known as Fusion. Fusionists gained control of the General Assembly in 1894, and, in 1896, elected Daniel Russell as the state’s first Republican governor since 1877. In 1897 Fusionists made sweeping changes to the city’s charter and state government in favor of African Americans and middle-class whites. Wilmington, the state’s largest city, sustained a complex, wealthy society for all races, with African Americans holding elected office and working in professional and mid-range occupations vital to the economy.

Furnifold Simmons led the State Democratic Party campaign of 1898. Josephus Daniels of the Raleigh News and Observer noted that Simmons used a three-prong attack to win the election: men who could write, speak, and “ride.” Men who could write created propaganda for newspapers. Men such as Alfred M. Waddell gave fiery speeches to inflame white voters. Men who could ride, known as Red Shirts, intimidated blacks and forced whites to vote for Democratic Party candidates. Democrats from across the state took special interest in securing victory in Wilmington. A group of white businessmen, called the “Secret Nine,” planned to retake control of the city and mapped out a citywide plan of action.

Further fueling the Democratic Party’s agitation was an article by Alex Manly, editor of the Wilmington Record, the city’s African American newspaper. Manly challenged white taboos regarding interracial sexual relationships, and his article became a tool used by Democrats to further anger whites. Democrats won the election, and the next day a group of whites passed a series of resolutions requiring Alex Manly to leave the city and close his paper, and called for the resignations of the mayor and chief of police. A committee of men led by Waddell was selected to implement the set of resolutions, called the White Declaration of Independence. The committee presented its demands to a Committee of Colored Citizens (CCC)—prominent local African Americans—and asked for compliance by the next morning, November 10, 1898.

Waddell met a crowd of men at the Wilmington Light Infantry (WLI) Armory at 8:00 a.m. on the tenth. Delayed response from the CCC and growing tensions led to a march by Waddell and as many as 2,000 whites to the Record printing office where they broke in and burned the building. By 11:00 a.m., violence had broken out across town at an intersection where groups of blacks and whites argued. Shots rang out and several black men fell dead or wounded—both sides claimed the other fired the first shot with two “witnesses” providing conflicting testimony.

Governor Russell called out the WLI, a home guard militia unit, and they marched into Brooklyn to calm the riot where they participated in skirmishes and killed several black men.

During the riot, members of Waddell’s committee plus George Rountree, John D. Bellamy, and others worked to facilitate a coup d’état to overthrow the municipal government. By 4:00 p.m., elected officials were forced to resign under pressure and were replaced by men selected by leading Democrats. Waddell was elected mayor by the newly seated board of aldermen. Additionally, leading African Americans and white Republicans were banished from the city over the next days. Besides the primary target of Alex Manly, men selected for banishment fit into one of three categories: African American leaders who were open opponents to white supremacy, successful African American businessmen, and whites who benefited politically from African American voting support. No official count of dead can be ascertained due to a paucity of records. At least 14 and perhaps as many as 60 men were murdered.

State and federal leaders failed to react to the violence in Wilmington. No federal troops were sent because President William McKinley received no request for assistance from Governor Russell. The U.S. Attorney General’s Office investigated, but the files were closed with no indictments in 1900. African Americans nationwide rallied to the cause of Wilmington’s blacks and tried to pressure President McKinley into action. However, many leading blacks were split on the best solution to the “Negro problem” and no nationwide campaign materialized.

Democrats solidified their control over city government through a new city charter in January 1899. Waddell and the board of aldermen were officially elected in March 1899 with no Republican resistance. The new legislature enacted the state’s first Jim Crow legislation regarding the separation of races in train passenger cars. A new suffrage amendment that disfranchised black voters was added to the state constitution by voters in 1900. The Democratic legislature overturned Fusion and placed control over county governments in Raleigh. New election laws limited Republican power in the 1900 election. Democrats controlled local and statewide affairs for the next seventy years after victory in 1898.

Inside Wilmington, out-migration following the violence negatively affected the ability of African Americans to recover. Black property owners were a minority of the overall black population before the riot, and property owners were more likely to remain in the city. An African American collective narrative developed to recall the riot and place limits on black/white relationships for future generations. White narratives claimed that the violence was necessary to restore order, and their narrative was perpetuated by most historians.
Wilmington marked a new epoch in the history of violent race relations in the U.S. Several other high profile riots followed Wilmington, most notably Atlanta (1906), Tulsa (1921), and Rosewood (1923). All four communities dealt with the aftermath of their riots differently. Whites in Tulsa and Atlanta addressed the causes and some effects of violence and destruction soon after their events; Wilmington whites provided compensation only for the loss of the building Manly’s press.

WILSON, WILLIAM JULIUS

1935–

William Julius Wilson is an African American sociologist who is most noted for his work in urban sociology and his study of the black urban underclass. He was born December 20, 1935, in Derry Township, Pennsylvania, and he received a BA from Wilberforce University, an MA from Bowling Green State University, and a PhD from Washington State University. He began his professional career at the University of Massachusetts at Amherst, where he wrote his first book on the African American community. He continued his research and wrote his most influential treatise while a professor at the University of Chicago. As of the mid-2000s he was Lewis P. and Linda L. Geyser University Professor at Harvard University.

In his book The Declining Significance of Race: Blacks and Changing American Institutions (1980) Wilson posits that although past racial oppression created an urban black underclass, the black class structure is now parallel to that of whites. Therefore, blacks’ life chances are now more a function of their economic class status than of race relations with whites. Consequently, race-specific programs such as affirmative action improve the life chances of middle-class blacks who are in the position to take advantage of the programs. Although Wilson does not deny the existence of racism, he suggests that programs designed to lessen the effects of poverty on all races, rather than race-specific policies, would better serve the needs of the urban black underclass, and are more likely to receive political acceptance.

Jack Niemonen (2002) argued that Wilson's historical analysis was underdeveloped, and that his concentration on aggregate labor market inequality underscores the effect of persistent racism and discrimination in the workplace. In addition, Wilson (1980) noted other reactions to his work. Political conservatives embraced Wilson’s theory as evidence of social pathology in the black community and as support for discontinuance of affirmative action–type programs. They attributed problems of the inner city such as high crime rates, poverty, and high rates of female-headed families to underclass culture and welfare policies. Sociologists criticized Wilson for his disregard of racism when segregation in housing and education still hampered opportunities for blacks, as well as for the perceived public-policy implications of his treatise. They sought evidence to counter Wilson’s claims of the existence of an underclass, and argued that social problems in the inner cities were caused by racism (summarized in Wilson 1980; 1987).

Wilson (1987) rejects liberal claims of racism and conservative claims of welfare policies and social pathology as the cause for inner-city social problems. Instead, he offers as explanation the economy-driven factors of urban black male unemployment, the male marriageable pool index (MMPI), social isolation, and negative concentration effects (negative consequences of the spatial and social isolation of impoverished African Americans). He also acknowledges some negative behaviors of ghetto inhabitants such as drug pushing and diminished work ethic, but continues to reject racism or social pathology as the cause (Wilson 1996). He posits that the global economy has a negative “domino effect” on the urban poor: When urban jobs are lost to suburbia and foreign countries, spatial and skills mismatch occurs, the tax base in the cities dwindle, public services such as education suffer, working- and middle-class blacks flee the city, and poorly educated blacks who possess no job skills eventually aban-
don their job searches for public assistance, and/or work in the illegal economy (Wilson 1996).

Critics argue that Wilson’s application of John Kain’s (1968) spatial mismatch hypothesis is limited for the following reasons: Residential segregation enhances the effect of spatial mismatch; employers’ decisions determine black employment in local jobs; there are numerous methodological inconsistencies; and because of the lack of black human capital and the simultaneous existence of immigrant social capital (Niemonen 2002). Another researcher, Michael Stoll, points out that racial discrimination contributes to the disparity between employment rate of suburban black males who reside in close proximity to available jobs and that of comparably educated white males (Stoll 1998). Others explain that the diminished work ethic earlier noted is a function of the lack of structural opportunities available to the black inner-city poor (Gould 1999) and the negative perception of employers towards inner-city black men (Kirschenman and Neckerman 1991). Mark Gould contends that if educational and employment opportunities become more available to the urban underclass, their attitudes towards work are likely to change as well (1999).

Finally, Wilson (1999) addresses the growing schism between the elite class and the dwindling middle class. He maintains that the middle and working classes, regardless of racial group, fail to see that racial division not only worsens the conditions of the black urban poor, it also exacerbates the political and economic disparity between the elite and nonelite classes. He recommends a grassroots multiracial coalition and affirmative opportunity programs based on merit that are neither race nor class specific.

Overall, Wilson’s major contribution to social science has been his illumination of the devastating effect that the global economy has had on the urban black community. Yet, his focus on class averts attention away from his agenda of improving the life chances of the ghetto inhabitants, as well as from the persistent racism and discrimination experienced by this group and other African Americans. Nevertheless, his scholarship redirected the academic community’s attention to the plight of the black urban poor.

**WILSON, WOODROW**

1856–1924

Thomas Woodrow Wilson was the twenty-eighth president of the United States of America. He served as president from March 4, 1913, until March 3, 1921. Wilson was born in Staunton, Virginia, on December 28, 1856, and died in Washington, D.C., on February 3, 1924.

Wilson was the son of a prominent Presbyterian minister and grew up in Georgia and South Carolina. Wilson attended Davidson College in North Carolina and was graduated from Princeton University in 1879. He studied law at the University of Virginia and earned a PhD in political science from Johns Hopkins in 1886. He later taught at Princeton and became its president in 1902.

Well-known for his support of progressive causes and his academic reforms at Princeton, Wilson was elected governor of New Jersey as a Democrat in 1910. Wilson attracted favorable national attention from progressive Democrats for his eloquence, integrity, and opposition to machine politics and from southern Democrats for his support of a “states’ rights” position that argued that Southern states should be free to pursue their own policies.
of racial segregation. Supported by former Democratic presidential nominee William Jennings Bryan, Wilson received the Democratic presidential nomination of 1912. Calling his progressive platform *the New Freedom*, Wilson emphasized a more competitive, decentralized economy, lower tariffs, and states’ rights. Wilson was elected president with 42 percent of the popular vote when most voters divided their support between Republican president William H. Taft and Theodore Roosevelt, the Progressive Party’s nominee and a former Republican president.

Wilson revolutionized the rhetorical role of the American president by personally addressing Congress about his legislative proposals and, later, conducting national speaking tours to promote his foreign policy. Wilson, however, also strengthened racial segregation in Washington, D.C., and admired the romanticized portrayal of the Ku Klux Klan in the silent film *Birth of a Nation*. In domestic policy, Wilson secured passage of major economic reform legislation. The Federal Reserve Act of 1913 decentralized and stabilized the national money supply by broadly distributing federal bank notes among several reserve banks. The Federal Trade Commission Act of 1914 promoted consumer protection and regulated interstate business behavior in order to eliminate, punish, and deter anticompetitive practices. Promoted by Wilson in order to prevent a national railroad strike, the Adamson Act of 1916 required an eight-hour workday for railroad workers.

Having adopted some of the Progressive Party’s 1912 platform through his legislation, Wilson was narrowly reelected in 1916 after he secured California’s electoral votes. His neutrality in World War I (1914–1918), summarized by the campaign slogan “He Kept Us Out of War,” also helped his reelection. After Germany resumed unrestricted submarine warfare in 1917 and tried to form an anti-American alliance with Mexico, Wilson secured a declaration of war from Congress on April 6, 1917.

Wilson believed that U.S. military and diplomatic efforts should be devoted to making World War I the “war to end all wars” and the war “to make the world safe for democracy.” In a speech to Congress on January 8, 1918, Wilson announced his Fourteen Points as the basis for establishing a just, lasting peace in Europe. These principles and objectives included national self-determination, freedom of the seas, and the creating of a League of Nations to enforce the peace after World War I. Unfortunately for Wilson, Britain and France opposed major elements of the Fourteen Points, especially national self-determination, which threatened their empires. Nonetheless, the League of Nations was included in the Treaty of Versailles of 1919, which officially ended World War I. For his diplomatic efforts, Wilson received the Nobel Peace Prize of 1919.

Some of Wilson’s critics perceived his egotistical, self-righteous refusal to compromise with Republican senators, especially Henry Cabot Lodge, to be the primary reason why the Senate rejected an active role for the United States in the League of Nations. While conducting a national speaking tour to increase public support for the League of Nations, Wilson suffered a severe stroke on October 2, 1919. The extent and nature of Wilson’s physical and mental disability were kept hidden from the vice president, cabinet, Congress, and the press by his second wife, Edith Wilson. As the Republicans prepared for landslide victories in the 1920 presidential and congressional elections, the nation experienced a Red Scare, labor disputes, and high inflation. After he left the White House in 1921, Wilson continued to live in Washington, D.C., until his death in 1924.

**WINNER-TAKE-ALL SOCIETY**

In conventional labor markets, reward is proportional to absolute performance, which in turn is generally modeled as proportional to human capital—an amalgam of talent, experience, education, training, and other factors that affect productivity. Thus, in the classic piece-rate scheme, a worker who assembles 101 widgets in a week gets paid 1 percent more than a coworker who assembles only 100. In contrast, a winner-take-all market is one in which small differences in performance often translate into very large differences in economic reward.

The winner-take-all perspective urges us to look first to the nature of the positions people hold, rather than to their personal characteristics. An economist under the influence of the human capital metaphor might ask: Why not save money by hiring two mediocre people to fill an important position instead of paying the exorbitant salary required to attract someone unusually good? Although...
that sort of substitution might work for jobs involving routinized tasks and flexible staffing arrangements, it often will not be feasible in the professions. Two average surgeons or CEOs or novelists or quarterbacks are often a poor substitute for a single gifted one. The result is that for positions for which additional talent has great value to the employer or the marketplace, there is no reason to expect that the market will compensate individuals in proportion to their human capital. For these positions—ones that confer the greatest leverage or “amplification” of human talent—small increments of talent have great value and may be greatly rewarded as a result of the normal competitive market process.

Technology has greatly extended the power and reach of the planet’s most gifted performers. The printing press let a relatively few gifted storytellers displace millions of village raconteurs. Now that we listen mostly to recorded music, the world’s best musicians can be everywhere at once. The electronic newswire has allowed a small number of syndicated columnists to displace a host of local journalists. And the proliferation of personal computers enabled a handful of software developers to replace thousands of tax accountants.

The dependence of economic reward on performance ranking is nothing new; what is new is the rapid erosion of the barriers that once prevented the top performers from serving broader markets. The global marketplace has been fostered by the reduction in trade barriers, vast improvements in information transmission and processing, the almost universal adoption of English as the language of business, and the emergence of a common popular culture.

Winner-take-all markets can be wasteful to the extent that they induce contestants for high rank to engage in costly and mutually offsetting investments to obtain positional advantage. In such cases, “positional arms control” schemes may reduce waste and improve economic efficiency. Such schemes range from market-specific policies, such as steroid bans for athletes and caps on the tax deductibility of executive compensation, to more general policies such as progressive income taxation.

WINNER’S CURSE
The winner’s curse story begins in 1971 when Edward Capen, Robert Clapp, and William Campbell, three petroleum engineers, wrote an article in which they claimed that oil companies suffered unexpectedly low returns “year after year” in early Outer Continental Shelf (OCS) oil lease auctions. OCS auctions are common value auctions where the value of the oil in the ground is essentially the same to all bidders. Bidders have their own estimate of the (unknown) value at the time that they bid. Even if these estimates are unbiased, bidders must account for the informational content inherent in winning the auction: the winner’s estimate of the common value is (one of) the highest estimates. If bidders ignore this adverse selection effect inherent in winning the auction, it will result in below normal or even negative profits. The systematic failure to account for this adverse selection effect is referred to as the winner’s curse: you win, you lose money, and you curse. (Unfortunately, many economists, particularly theorists, characterize the winner’s curse as the difference between the expected value of the item conditional on the event of winning and the unconditional, naive expectation, using the term to refer to bidders fully accounting for this difference, rather than failing to do so and losing money as a consequence.)

Similar claims regarding a winner’s curse have been made in a variety of other contexts: book publication rights, professional baseball’s free agency market, corporate takeover battles, and real estate auctions (see chapter 1 in John H. Kagel and Dan Levin’s 2002 book Common Value Auctions and the Winner’s Curse). These claims have traditionally been greeted with a good deal of skepticism by economists as they imply that bidders repeatedly err, thus violating basic notions of economic rationality. It is exceedingly difficult to support claims of a winner’s curse with field data because of data reliability problems and plausible alternative explanations.

The ambiguity inherent in interpreting field data, and the controversial nature of the winner’s curse, provided the motivation for experimental investigations on the subject. Initial experiments conducted by Max H. Bazerman and William F. Samuelson in 1983 showed that inexperienced bidders are quite susceptible to the winner’s curse in a corporate takeover game. John H. Kagel and Dan Levin found similar results in 1986 in first-price sealed-bid common value auctions. Subsequent experiments have focused on the robustness of the phenomena and features of the environment that might attenuate its effects. Does the commonly known presence of an “insider” who knows the true value of the item attenuate the winner’s curse? (No, it does not.) Do open outcry (English) auctions in which bidders with higher value estimates gain information as a consequence of lower valued...
bidders dropping out attenuate the winner’s curse? (Yes, to some extent, but this experience does not transfer into doing better in sealed-bid auctions.) Are subjects who have learned to avoid the winner’s curse in auctions with relatively few (four) bidders able to avoid it in auctions with larger numbers of rivals (seven) with its more severe adverse selection effect? (No, they are not.) Thus, although bidders are able to avoid the winner’s curse with enough experience, this learning appears to be context specific, so that it does not easily generalize to related environments.

Research has also focused on key public policy issues. As theory predicts, public information that is correlated with the common value raises seller’s revenue in first-price sealed-bid auctions in the absence of a winner’s curse (i.e., for experienced bidders), but contrary to the theory lowers revenue for less experienced bidders who still suffer from a winner’s curse. English auctions, where public information is released endogenously, have the same effect. Finally, there are striking parallels between laboratory outcomes and anomalous findings from field data, along with experiments in which experienced industry executives in the laboratory suffer to the same extent from the winner’s curse as do student subjects, which lead most scholars and a number of other observers to believe that the winner’s curse is alive and well both inside and outside the laboratory (Kagel and Levin, 2002).

WIZARD OF OZ

The book The Wonderful Wizard of Oz (1900) and its film adaptation The Wizard of Oz (1939) quickly became a foundational element in American popular culture with countless idiomatic allusions, cultural references, and pervasive merchandizing. Lyman Frank Baum wrote seventeen sequels comprising the Oz series, though none repeated or surpassed the popularity of the first book. The film launched actress Judy Garland’s stardom; she won an Academy Award and made the song “Somewhere Over the Rainbow” popular and famous, earning it recognition as the number one song of the twentieth century. Since the 1950s, the film has aired continuously on network and cable television. These airings, with few exceptions, became an annual tradition and continued through 2002. Sidney Lumet directed an African American stage version in 1978; The Wiz starred pop-music icons Diana Ross and Michael Jackson as Dorothy and the Scarecrow, respectively. In 1998 The Wizard of Oz ranked sixth out of one hundred in an American Film Institute poll; it was the highest ranked musical in the genre of fantasy and family movies. Through the first half decade of the 2000s, it continued to generate academic and mainstream books, journal articles, CD music releases, videocassette releases, websites, blogs, merchandizing, and a remastered digital DVD release.

Baum was born on May 15, 1856, in Chittenango, New York. He suffered a stroke and died on May 5, 1919. Many biographies exist detailing his life and work. The success of the Oz books prompted a musical adaptation for the stage. Oz (1902) became very popular and toured for nine years. The film The Wizard of Oz was adapted from Baum’s first book, other books in the series, and stage scripts.

The basic storyline details the adventures of a young girl named Dorothy as a tornado transports her and her dog to the magical land of Oz, where she encounters and befriends interesting characters and experiences a range of adventures, some of which are frightening, even gruesome, and others humorous. The characters most remembered are Dorothy; her dog Toto; the Munchkins; the Scarecrow; the Tin Man; the Cowardly Lion; the Wizard of Oz; Glinda, the Good Witch of the North (Glinda is from the South in the book); and the main villain, the Wicked Witch of the West. The film is mostly true to the original books, though one key difference is that the land of Oz and the Emerald City are real places in the books, but the film indicates that these places are fantasy and only exist in Dorothy’s dream, which occurs as a result of a bump on the head. This notion is portrayed through the contrast of the dual-tone sepia segments, which depict real-life Kansas, and the Technicolor® segments, which depict the land of Oz. Also, the same actors who play the role of the farm hands play the roles of the major land of Oz characters.

The most noted dialogue that has worked its way into American popular culture includes the sayings: “Toto, I’ve
got a feeling we’re not in Kansas anymore,” “Follow the yellow brick road,” and “Pay no attention to the man behind the curtain.” The first line has appeared in many variations in movies, television sitcoms, and skits. One of the most famous yellow brick road references is pop singer Elton John’s 1973 album *Goodbye Yellow Brick Road.* “The man behind the curtain” has been used in reference to conspiracy theories and political scandals, including the Kennedy assassinations, Watergate, Iran-Contra, and suspicions of voter fraud in the 2000 U.S. presidential election.

There have been several scholarly interpretations of the story and film, including Daniel Dervin’s 1978 Freudian interpretation, in which Dorothy’s journey is symbolic of a sexual coming of age; Darren John Main’s 2000 Jungian interpretation, in which Dorothy’s journey is emblematic of archetypal spiritual journeys; and Lynette Carpenter’s 1985 analysis, which presents the film as embodying U.S. isolationist tendencies during the dawn of World War II. The most acclaimed interpretation is Henry M. Littlefield’s 1964 view of the story as allegory for the gold versus silver standard debate, political populism, and William Jennings Bryan’s presidential run. For Littlefield, “*The Wonderful Wizard of Oz* has provided unknowing generations with a gentle and friendly Midwestern critique of the Populist rationale…. [L]ed by naive innocence [Dorothy] and protected by good will [Glinda], the farmer [Scarecrow], the labourer [Tin Man] and the politician [Bryan in particular] approach the mystic holder of national power [the Wizard] to ask for personal fulfilment” (pp. 57–58).

Another Populist perspective exists between the film and the New Deal. The lyricist for all the songs in the film was E. Y. “Yip” Harburg (1896–1981), who wrote the Great Depression anthem “Brother, Can You Spare a Dime?” He also helped shape most of the story. Harburg claimed that the Emerald City represented the New Deal. In 1990 Francis MacDonnell extended this interpretation, stating that the Wizard represents New Deal president Franklin D. Roosevelt. In the same way that the Wizard shows Dorothy and her friends that they always had the qualities they were in search of, President Roosevelt demonstrated that the American people held the solutions to their problems and restored their self-confidence.

**WOLF, ERIC**

**1923–1999**

Anthropologist Eric Robert Wolf was born in Vienna, Austria, in 1923 and died in Irvington, New York, in 1999. The son of an Austro-Russian marriage, Wolf passed a cosmopolitan childhood in Vienna and the Sudetenland before being sent to school in England as Adolf Hitler’s (1889–1945) destruction loomed. After emigrating with his parents to New York, he served in World War II (1939–1945). After the war, Wolf completed his undergraduate degree at Queens College (1946) and a PhD at Columbia University (1951), both in anthropology. Along with returning veterans such as Morton Klass (1927–2001), Robert F. Murphy (1924–1990), Stanley Diamond (1922–1991), and others, Wolf formed the Mundial Upheaval Society to discuss the influence of classical social theory, especially Marxism, in the social sciences. During early fieldwork in Puerto Rico and Mexico, Wolf combined Maxian and Weberian frameworks with Middle European political-economic debates arising from the 1917 Russian Revolution, examining the praxis of grounded power relations. From this work emerged contributions to anthropologist Julian Steward’s (1902–1972) *People of Puerto Rico* (1956), and Wolf’s classic *Sons of the Shaking Earth* (1959), which synthesized archaeological and ethnohistorical knowledge of Mesoamerican civilization within a class-sensitive framework. Wolf also authored or coauthored groundbreaking articles that addressed the history and sociology of cultural forms—for example, the Virgin of Guadalupe, *compadrazgo,* corporate communities, and Santa Claus—as these forms build liens of redistribution across class, caste, and nation. In early publications as in later ones, Wolf...
served as a translator of European social thought into American anthropology.

Over a long and distinguished teaching career at the universities of Illinois, Virginia, Chicago, and Michigan, and at Lehman College at the City University of New York Graduate Center, from which he retired in 1992, Wolf was a prolific and iconoclastic scholar, publishing more than one hundred articles, and editing many journal issues and books. In addition to Sons of the Shaking Earth, his books include: Anthropology (1964), Peasants (1966), Peasant Wars of the 20th Century (1969), The Human Condition in Latin America (1972, with Edward Hansen), The Hidden Frontier (1974, with John Cole), and the magisterial Europe and the People Without History (1982), followed by Envisioning Power (1999). Pathways to Power, edited with his wife, the anthropologist Sydel Silverman, appeared posthumously in 2001. All illustrate coherent themes central to his scholarship: connections between intellectual histories and social movements and broad political economic trends; ties binding specific cultural forms to class-inflected power relations; and embedded local class relations that play out articulations of global history. Thus, the daily political and social lives of family, community, faction, religious-ethnic group, state, and nation may appear as somewhat autonomous, but in Wolf’s writings they all serve as termini of concrete international processes. His work underlines the historical depth of these interconnections within and across shifting national boundaries of modernity, and he insists on the historical incorporation of the small-scale societies anthropologists conventionally study into larger webs of power, exploitation, and occasionally resistance. It is Wolf’s enduring achievement to have enabled individuals to understand such societies in new ways, as dependent on connections of political economy and culture.

In Anthropology, Wolf labeled his field “the most scientific of the humanities, the most humanist of the sciences” (1964, p. 88). Later texts carried humanist scientific study into the interstitial connections throughout modern history. His synthetic intelligence and highly comparative method enabled Wolf to produce books that remain beacons of social scientific clarity in anthropology. Peasant Wars of the Twentieth Century (1969) illuminated the limited, class-fragmented, and constrained agency of the peasants who helped to topple and transform regimes in Mexico, Russia, China, Vietnam, Algeria, and Cuba, too often at their own expense. Europe and the People Without History (1982) showed that the bands, tribes, and villages once considered classical anthropological subjects were actually products of the socioeconomics of the modern capitalist world. After its publication, anthropologists could never again work in the “ethnographic present.” It was Wolf’s accomplishment, as the subtitle of his last book forcefully proclaims, to have oriented his field toward Building an Anthropology of the Modern World.

WOMANISM

An ongoing concern for black feminists has always been that their specific experiences have been elided within a discourse that is biased towards a white, Anglo-American perspective. It is a view clearly enunciated by Audre Lorde’s essay “An Open Letter to Mary Daly” (1984) in which she castigates the radical feminist philosopher for her misrepresentation of black women in her book Gyn/Ecology (1978), which Lorde claimed, “dismissed my heritage and the heritage of all other noneuropean women” (69).

But in 1983, in which Lorde published her address to Daly, the writer Alice Walker published what was to prove an extremely influential essay, “In Search of Our Mothers’ Gardens” (1983) in which her central concern was to formulate a definition of black feminism from within African American culture itself. Whereas Lorde argued that Daly portrayed black women only as victims, ignoring their power as active agents capable of combating their own oppression, Walker focused on precisely those positive aspects, developing a feminist terminology drawn from everyday discourse used in the black community.

Although the term womanist is now synonymous with Walker’s essay and book by the same title, it was not new to the English language. According to the Oxford English Dictionary, the term womanism first appeared in 1863, indicating “advocacy of or enthusiasm for the rights, achievements, etc. of women.” In the context of second wave feminism, however, “womanism” has become
more specifically aligned with the black feminist movement. Walker's use of the term "womanism" therefore etymologically relates directly not to its prior usage in the nineteenth century but to the colloquial term womanish, which Walker defines as "Opp. of 'girlish,' i.e., frivolous, irresponsible, not serious." A "womanish" girl is wilful, inquisitive, and wise beyond her years, refusing to accept rules and limitations imposed by others.

However, although Walker draws the concept of womanism from, and defines it through, a black cultural context, she intends it to be inclusive rather than exclusive, offering four increasingly poetic understandings of the word that stress its connectedness to wider experiences of feminism. Although she begins with the black folk usage of "womanish," her second description expands the term to designate any woman, of any color, whose primary identification is with other women, either sexually or nonsexually. Nevertheless, a womanist is not a separatist but someone who is a "universalist," committed to "wholeness of entire people, male and female" (xi). She thus harmonizes two contradictory subject positions: a dedication to personal freedom along with an acknowledgment of the innate interconnectedness of peoples and genders. Walker's third definition stresses this balance between separation and association, identifying a womanist as someone committed to sensual gratification but also political struggle; to herself and to the wider community within which she is situated.

It is for this reason that "womanism" has become a widely used term within feminist theory, for it allows black women to articulate their feminism without relinquishing an attachment to black culture and racial politics. The subtle distinction between feminism and womanism is best summed up by Walker's final definition: "Womanist is to feminist as purple to lavender" (xii), and is exemplified in a speech delivered over a hundred years earlier. When Sojourner Truth, speaking at the Women's Convention in Akron, Ohio in 1851, proclaimed 'ain't I a woman?,' she asserted her rights not only as a woman, but also as an African American, an ex-slave, and a political campaigner.

WOMEN

A definition of “woman” that applies cross-culturally, one that includes the definitions offered by societies that are not part of our own Western/industrial tradition, will inevitably include some allusions to female physiology and to cultural constructions that include women's reproductive role, spiritual role (or its absence), domestic role, work role, and role in the care of children, assigning varying degrees of importance to each. The definition of womanhood may or may not be related to a society's definition of manhood, and may or may not be related to other gender categories that a society might recognize—which can be as many as five.

Furthermore, the definition of “woman” and “womanhood,” when viewed from a cross-cultural perspective, will vary depending upon three variables. The first variable is the society's recognition of the specific stages of the female life course. Societies differ in how they identify and define the physical and psychological maturation stages of a woman's individual development. Some stages that we may readily identify in our own society (such as getting a driver's license) do not exist or are ignored, while other developmental events are given exaggerated attention and some are of such importance that they are accorded ceremonial recognition. The second variable, the society into which the individual is born (or of which she may become a member by a choice made later in life), will provide a variety of cultural expectations, some of which every individual female member is expected to meet and some of which only a chosen few may achieve. The third variable consists of the time period in the history of a particular society in which the individual finds herself. These three variables are not necessarily independent but can interact with each other to provide the specific definition of what it means to be a “woman” for a female individual of a particular age, in a specific society, and at a particular moment in history.

THE FIRST VARIABLE: THE LIFE COURSE

In all societies, the infant's sex is noted at birth, and in some societies, a female identity may lead to immediate infanticide. Yet often the baby is viewed as virtually neuter, in contrast to our own society, in which even the tiniest infant garments are gendered. Recognition of the individual's gender can begin at various stages early in the life course, but by the time signs of adolescence appear, the individual has been assigned. Although some societies
Women

did not particularly note menarche or other evidences of adolescence, in many traditional societies, mere girls could only “be made into women” by means of an elaborate ritual. In these societies, only the initiated conformed to the definition of “woman.” Such ceremonies, sometimes celebrated individually at the time of menarche and sometimes celebrated for groups of girls at the approximate onset of their adolescence, took a variety of forms. Some were elaborate, involved considerable expense for the family of the girl, engaged the entire community, and took months to complete. In other societies, the observance was brief, involved only a few female relatives, and was somewhat private.

In the ceremony of the Bemba of east Africa as reported by Richards (1935), men actually had specific roles to perform in the initiation. In many other societies, men are banned from even seeing the ritual. Among the Bemba, there were tests of competence for the initiates, and it was believed that their roles as food providers would be performed with the appropriate, womanly attitude after the completion of the long, elaborate ceremony. (In contrast, our own educational system typically focuses on transmitting skills and tends to neglect training for the proper attitude toward work.) Several ceremonies performed in other traditional societies included a painful genital operation, but most female initiation rites provided instruction, often regarding sexual activity, as well as a period of seclusion during which the initiate had to observe a number of taboos. These rites were typically followed by feasting, receiving gifts and new clothes, and being declared beautiful and ready for marriage negotiations to begin.

The life course of women can be viewed as discontinuous even if no ritual activity creates a major change in what it means to be a woman. Thus the end of virginity, menarche, the arrival of children, and menopause are one and all irreversible phases of womanhood that are not only physical but also have psychological and cultural meaning. The recognition or lack of recognition a society provides for these physiologic milestones in the lives of women varies cross-culturally. Thus, for example, as reported by Meigs (1984), the Hua of Papua New Guinea were a society in which not only the physiological changes characteristic of the female life course but also culturally constructed changes without a biological basis created a fluid definition for Hua womanhood. The body of Hua women and girls were believed to be filled with a vital essence that was both polluting and to some degree dangerous to men and that was transmitted to men through each act of sexual intercourse and through the food that women handled, prepared, and served. The essence was drained from women’s bodies in the act of childbirth. Thus an older woman, the mother of several children, became as pure as a man, while aging men became impure like women. Because many older women were pure like men, they could have access to the great men’s house, which was forbidden to women and children. Unlike them, she might have participated in male activities and had access to secret male knowledge. Thus among the Hua, the meaning of womanhood was not based only on physiological changes that characterize the female life course but depended on the culturally constructed definitions assigned to these female life courses stages.

THE SECOND VARIABLE: SOCIETY

In many societies the definition of womanhood is shaped by the view that women are physically weaker and intellectually inferior to men, as well as spiritually underendowed. In some societies the definition must take account of the fact that women are viewed as naturally lecherous and wanton. Rape, wife abuse, and even murder are viewed as justifiable responses to these female tendencies. Women’s sexual impulses are corrupting to men and constantly threaten the honor of the family, requiring the unremitting vigilance of a brother or a husband. Women of childbearing age in such societies must be restrained by perpetual chaperonage, by the alert supervision of elder female kin, and by confinement, an enforced claustrophobia, lived in the company of other women.

In spite of the negative valuation that was part of the definition of women in many societies, there was also evidence of envy by men. Among the Inuit of the central Arctic, women’s lives were confined to the igloo during the long winter. Unconfined, the men ranged freely from the camp to hunt and fish, yet they envied the shelter and warmth of the women’s indoor life. An attempt to imitate women that may have been based on envy was the periodic self-inflicted bleeding practiced by the men of several Melanesian societies. In a private ritual, a man would scrape his penis to induce bleeding, an imitation of women’s menstruation, which was believed to provide strength and well-being. An example of a positive valuation of women comes from the traditional Native American societies of the Gulf region, where there were separate languages for men and women and men felt the women’s language was more beautiful than their own.

Women’s Economic Role Whether or not the men of a particular society envy women, or whether or not the members of a society subscribe to a definition of womanhood that attributes inferiority to women, or whether or not members of a society have a more egalitarian view of the sexes, womanhood is inevitably defined in part by the work women perform (unlike our own society, where it would be unusual for a definition of womanhood to include references to specific vocations.) Thus among the traditional Iroquois of New York State, raising the crops
upon which the people's livelihood depended was the work of women. A man working in the gardens was either too old and too frail for male activity or he was a prisoner of war compelled to perform humiliating, inappropriate work. Thus, for example, the Iroquois “made women” out of the defeated Delaware by making them work in their gardens. Yet the productivity of the Iroquois women was revered. Female spiritual beings represented the crops, and ceremonial activity celebrated the cultivated foods provided by women, not the hunting and warfare of the men.

Competence in women's work was valued so highly in many traditional societies that it overshadowed sexual attractiveness in the choice of a wife. Thus, among the Iroquois and the traditional Inuit, an older competent woman might be viewed as a desirable wife for a far younger man. Productivity, diligence, and highly developed female skills were among the qualities that were accorded the privilege of being a “manly hearted woman” among the North Piegan, a Canadian Blackfoot tribe, according to Lewis (1970). Although most married women in this society served as lower or “slave wives,” the “manly hearted woman” was the “sit-by wife.” She was not masculine, as the title might suggest; instead she excelled in women's work and was therefore an economic asset. She was the favorite wife, actively sexual and outspoken. Lower wives were beaten mercilessly for such behavior in traditional times.

As reported by Elam (1973), the traditional Hima, east African herders, further illustrate how the work women perform and their sex life define womanhood in a particular society. In traditional times, Hima girls joined the herders with their cattle outside the village. They acted as assistants to the men in activities such as milking. They were physically active and free to move about the landscape and were expected to be chaste until marriage. The wife, in contrast, was confined to the hut. Unlike girls, she was heavily clothed and her diet and lack of physical activity were intended to make her fat, which was viewed as sexually attractive. Fat and desirable, she was expected to grant sexual favors to numerous men, including her father-in-law. Unlike girls, she was forbidden to milk, bleed, or slaughter cattle. In her life as a woman, she was by definition confined, and her work consisted of making butter and curd and keeping the milk jugs clean.

Women's Spirituality In many societies, the definition of womanhood that pertains to most of a woman's life, the childbearing years, appears to exclude the possibility of spirituality. Thus among the traditional !Kung of southern Africa, pregnancy and lactation were viewed as incompatible with trance, since such spiritual activity could harm the unborn child or the nursing infant. In parts of North America, a woman could become a shaman, and a spiritual being would enable her to attain special powers. But in many societies only a man could be a shaman. Among the Navajo, it was believed that the evil powers of witchcraft were inaccessible to a woman of childbearing age. Thus the ability to exert spiritual power or the absence of this ability is noted in the definition of womanhood in many societies. In contrast, spiritual attributes are typically not part of a definition of womanhood in our own society.

THE THIRD VARIABLE: HISTORIC FACTORS

A society's definition of womanhood inevitably evolves to reflect historical changes. This is as true for our own society as it is cross-culturally. In the later twentieth century, historical changes have created a redefinition of womanhood in the Western/industrial world that is almost as dramatic as the redefinition of womanhood created by the end of colonialism and the spread of globalization in those parts of the world that are not part of our own tradition. An example of such changes is offered by Draper (1975) in her description of the !Kung of southern Africa. Their traditional way of life had continued into the mid-twentieth century, and although aware of the outside world (a world that mistakenly believed they were extinct), they had retained a traditional definition of womanhood. The women of the !Kung sustained the life of the small, migratory camps with their food-gathering activities. Each day that the women set out into the Kalahari Desert, they were successful in harvesting the vegetable foods that constituted the major portion of the !Kung diet. While collecting, the women also gathered information about the movement of animals, which they provided to the men to help them in their hunting. The hunting activities of the men, though less frequently successful than the gathering activities of the women, received a great deal of cultural attention and provided the food that was harder to obtain, made up less of the diet, and was more highly valued. Although the gathering activities of women were not accorded particular recognition, women had the right to be outspoken, and the relationship between men and women was markedly egalitarian. These traditional circumstances have been attributed to women's economic importance. And this in turn was made possible by a benign environment, in which women were not threatened by enemy neighbors or wild animals that might have made male protection necessary. Their autonomy made possible the traditional !Kung women's role as the “major breadwinners.”

Dramatic and rapid changes occurred when the !Kung became sedentary, living on the outskirts of the villages of herders, who now controlled the region. !Kung women became housewives. The open camps were
replaced by huts which isolated women from relatives and neighbors. Their economic importance was a thing of the past, as was their autonomy. Wife abuse was now a problem. This vastly oversimplified history of the !Kung during the later twentieth century illustrates how a particular society's definition of womanhood can undergo dramatic change. Although still living in their homeland, their new circumstances totally altered how “woman” was defined.

CONCLUSION
The definition of “woman” is only partially based on the physical traits that differentiate the sexes. Superimposed on physiological reality is the possibility that a society may recognize more than two genders. In addition, the definition a culture constructs for the term “woman” may change during different stages of the life course, for example, by not including the category “uninitiated female adolescent” as part of the definition of “woman.” Different societies also vary on which aspect of womanhood the culture stresses in its definition. Is it her economic role? Is it her maternal role? Is it her sexual role? Is it her domestic role? (For a review of the interrelationships of these factors, see Brown 1973.) Or perhaps it is her physical or mental inferiority and lack of spirituality compared to men. Historical changes can alter a society’s definition. And all of these possible aspects of a society’s definition of “woman” can be interdependent and influence each other. The cross-culturally applicable definition of any concept is inevitably complicated, but the necessary ingredients of the varied definitions can be identified.

WOMEN AND DEVELOPMENT
SEE Gender and Development.

WOMEN AND POLITICS
From an international perspective, the scholarship of women and politics focuses on issues of women’s participation and representation in governmental institutions, the legal right over decisions concerning reproduction and sexuality, and the effects of globalization on women’s work and social movements.

POLITICAL PARTICIPATION AND REPRESENTATION
Issues of participation and representation of women in politics (political empowerment) are centered in the ideology of the Enlightenment period of the mid-eighteenth century and, therefore, the idea that equal political participation and representation of women in local, state, and federal governments will challenge gender inequality. American feminists were at the forefront of this movement arguing in the 1920s and then in the 1970s for suffrage and equal treatment, respectively. The United Nations (UN) promoted the importance of political empowerment for women as evidenced by the UN’s observance of a Decade for Women (1976–1985); the UN’s agenda for the political empowerment of women set forth in *The Beijing Declaration and Platform for Action* (1995); a UN treaty based on *The Universal Declaration of Human Rights* and embodied in Article 25 of *The International Covenant on Civil and Political Rights* (1976); and the convening of delegates at the *Convention on the Elimination of All Forms of Discrimination Against Women* (1967) to discuss the political rights of women around the world. The liberal political theory that informs the UN’s politics embodies the ideas that (1) political systems are undermined and illegitimate when women are underrepresented; (2) the representation of women in politics contributes to an inherently more democratic multi-party system; (3) gender reform lies in legal reform; (4) “special treatment” (e.g., maternity leave) reproduces gender inequality; (5) a “critical mass” of women represented in governments ensures gender equality; (6) states should legally protect women from discrimination in all areas of
social life; and (7) women have a civil right to representation and their political participation serves as role model behavior and influences the status of women outside the political body.

Critics of the idea that representation and participation challenge gender equality argue that (1) women’s participation and representation do not necessarily translate into a representation of women’s interests, (2) feminist priorities need to be reinforced in structures and networks (with non-governmental organizations and women’s committees within legislative bodies) in order for change to occur and (3) the presence of women in politics does not ensure a feminist political platform. All women, in other words, are not feminists. As a response to the underrepresentation of women in politics, quotas ensuring the participation of women have been suggested and imposed (e.g., France established party laws in 2000). In 2004, the Inter-Parliamentary Union reported that only 15.6 percent of governmental bodies around the world were represented by women. Women represented 6.8 percent in the Arab States, 18.6 percent in the United States, and 39.7 percent in the Nordic states.

RIGHTS OVER REPRODUCTION AND SEXUALITY

The political struggle over rights to abortion, contraception, and the female body has characterized feminist movement around the world. In the United States this is characteristically exemplified by the legalization of abortion in 1974 (Roe v. Wade). In the Middle East, North Africa, India, and parts of Southeast Asia, the political struggle over reproduction and sexuality is framed in discourses about the high incidents of female genital mutilation, honor crimes, sex trafficking, bride burning, marital rape, and sexual abuse.

In the Middle East and North Africa (MENA), feminists argue, family law (called in the region “personal status law”), as well as criminal law is informed by traditional and patriarchal cultural norms, thereby legitimizing the violation and control over women's bodies and rights. In neo-Islamic states, such as Iran, religious scholars are increasingly informing the legal code. Global feminists have argued that laws in MENA have allowed for violence against women, statutory discrimination, and disproportionate punishment for women. Women’s movements in MENA are demanding political equality, the ability to contract and register their own marriages, a right to divorce, and justice in cases of rape or sexual abuse. Not only the state, but families and local communities have great control over women's sexuality and reproductive rights. “Honor killings”—the murder of a woman by a male family member for a violation of the social norms of sexuality—exemplify the control family has over the sexuality of daughters. Sometimes the families, including mothers, gather and plan the murder of a daughter. Feminists in the region, scholars of women in MENA, as well as global feminists recognize the role of family and community over the control of women and seek to criminalize behavior such as “honor killings” that are often treated as private rather than public matters.

GLOBALIZATION

The effect of globalization on the status of women is a central theme in the study of contemporary women worldwide. Globalization is defined as the movement toward global capitalism and culture. Scholars have explored the negative and positive effect of globalization on women cross-culturally. Critics of globalization point to policies that buttress the industrialized monetized sector of the economy, thereby favoring work performed by men at the expense of informal modes of work performed by women, particularly in the developing countries. According to this perspective, public subsidies that support social programs for women and children are diminished as nations struggle to pay off high interest loans to industrialized nations.

In Latin America, as a response to the weakening economic position of women, political collectivities of women have organized around the demand for greater provision of public services such as running water, electricity, transportation, day care and health services (all sorely lacking in squatter settlements in which poor women live). The women have also protested against the rising price of food. Often these women defend their right to a decent living on the basis of their status as “mothers,” “housewives,” or both. These types of social collectivities have been criticized by feminists who favor “equality” and “no special treatment” over supporting women in their traditional roles. Conversely, women activists engaged in informal social movements sometimes separate themselves, by way of identification, from woman activists who are more concerned with mainstream political participation and representation (“equality” and “no special treatment”). Since the period of advanced economic globalization, Latin American women have mobilized along with men in labor unions; yet, unions, it has been argued, continue to be regarded as a male sphere where women only serve as supplementary workers.

Other scholars believe there are positive effects to globalization such as women’s political representation (in formal governmental institutions), the liberalization of traditional gender roles, and increased education. As a result of these positive effects, they argue, the political presence of women has increased dramatically in the beginning of the twenty-first century. For example, in January 2007 in Chile’s presidential run-off Michelle
Bachelet was elected the first female president of Chile. Other Latin American women have made inroads into state power. The Brazilian constitution of 1988 formed The Council on the Condition of Women (subsequently named The National Council on Women's Rights), which implemented a family planning program; extended maternity leave; facilitated the establishment of a special police force to end sexual abuse and domestic violence; ended the prohibition of abortion; and successfully promoted a women's agenda.

The democratization and the rise of civil society often attributed to globalization further increased Latin American opposition groups. In 1988, Chilean women fought against President Augusto Pinochet's (1915–2006) military authoritarian rule and demanded the recognition of human rights. The Mothers of the Plaza del Mayo in Argentina played a decisive role in the defeat of the dictatorship there. On the basis of their status as mothers, sisters, daughters, The Mothers of the Plaza del Mayo protested the disappearance of their sons, brothers, and husbands.

The UN's Human Development Program has recognized the need for a broad understanding of gender that includes not only the role of politics, but economics and cultural interpretations of women's and men's roles on the lives of women throughout the world. Consequently, in 1995 they created the Gender Empowerment Measure, which measures gender equality/inequality on the basis of decision-making power, and political and economic participation.

**WOMEN’S LIBERATION**

The term *women’s liberation* in twentieth-century discourse has been used interchangeably with feminism, women’s rights, and the women’s movement. A more precise focus on the term *women’s liberation* raises the question, “Liberation from what?” The response that feminists have offered is liberation from the oppressive practices of patriarchy and women’s second-class social status that have been a part of the structure of traditional and modern societies. The concept of women’s liberation was popularized by the early stages of the Second Wave of the women’s movement, by the United Nations’ (UN) decade of focus on women (1975 to 1985), and more recently by UN-sponsored events like the 1995 Beijing Conference on Women. Because women constitute 50 percent of the world’s population, the potential for coalitions across nations, ethnicities, ages, classes, religions, and sexualities is significant for all people. These UN events, which included governmental and nongovernmental agency representatives, have offered opportunities for international networking to supporters of the women’s movement. The term *liberation* draws insights from Marxist and liberal democratic theories, which argue that societies work best when all adult persons are free and able to participate fully in public life. But what counts as women’s liberation shifts over time.

**HISTORIC OVERVIEW**

Historically, the women’s movement can be divided into three waves, which begin with the issue of suffrage. Setting the stage for the First Wave were some key political writings in Western societies that articulated the centrality of individuals in the state. These include the eighteenth-century work of Mary Wollstonecraft (1759–1797), *A Vindication of the Rights of Woman*, the nineteenth-century work of John Stuart Mill (1806–1873) with Harriet Taylor (1807–1858), *On the Subjugation of Women*, which compares women’s situations to slavery; and the work of the German socialist Friedrich Engels (1820–1895), *Origins of the Family, Private Property, and the State*, shaped by his work with the political philosopher Karl Marx (1818–1883), which argues that women’s oppression begins with the division of labor in the family.

The women’s movement has developed in a variety of world cultures in complex ways, but an understanding of the Western tradition offers a context from which to examine some of the key issues. For those influenced by U.S. politics, the First Wave began with the Seneca Falls Convention in New York in 1848, when activists involved in the abolition of slavery met to talk about women. It ended in 1920 with a U.S. constitutional amendment that granted women the vote. The Second Wave began with...
the civil rights struggles in 1962 and included a push for an equal rights amendment, workplace equity, educational opportunities, and policies that supported women's participation in public life. During this period women's studies programs were established as challenges were made to traditional discipline-based theories and epistemologies. In the early 1980s the New Right began to gain momentum just as feminist goals were shifting from legal rights to cultural issues and as multiculturalism was gaining greater recognition. These developments gave rise to the Third Wave of feminism in the 1990s, which has gained momentum since the beginning of the twenty-first century.

The Seneca Falls Convention was organized by Lucretia Mott (1793–1880) and Elizabeth Cady Stanton (1815–1902), with the abolitionist Frederick Douglas (1817–1895) and various Quakers in attendance. The issues in the First Wave were laid out at the convention in the Declaration of Sentiments, which called for women to have access to education, to their own salaries, to courts, to property, to child custody, to employment, to professions, and to the right to vote, which was the most controversial resolution. It would take from 1848 to 1920 for this last resolution to be achieved in the United States. The struggles for women's equality in European societies followed similar historical paths.

THE SECOND WAVE

The Second Wave of American feminism grew out of the civil rights movement of the 1960s and the New Left. During the early stages activists readily employed the term women's liberation as a way of explaining that the problem women faced as a group was similar to that of other oppressed groups. Second Wave consciousness-raising groups helped women move from seeing themselves as ineffective individuals in a fair society to identifying the structural patterns of sex bias that turned women as a group into second-class citizens. Women were in need of liberation from patriarchy and the cultural, legal, and political practices that flowed from patriarchy to subordinate them. As the civil rights movement progressed and the women's movement gained supporters, four key categories became the base for critical analysis: race, class, gender, and sexuality. The removal of their accompanying social ills—racism, class privilege, sexism, and heterosexism—would liberate societies from oppressive practices and unjust institutional structures. Feminists argued that women's liberation would result in the liberation of men because gender roles would be more open and individuals could assume them according to their talents and tastes instead of the shape of their bodies.

The Second Wave of feminism was supported by a variety of local and national political organizations that pressed for such rights as to continue work while pregnant and to have access to information about birth control, to abortion, to health care for pregnant women, and to legal protection from domestic violence, rape, sexual harassment, and economic discrimination. Concerns over women's health, reproductive choices, and body image came to the foreground as the issues of health and medical practices were scrutinized for sex or gender bias. Groups used lobbying, demonstrations, community-based organizations, and litigation and were loosely linked together through national-level organizations like the National Organization for Women (NOW), founded in 1966.

Betty Friedan (1921–2006), one of the NOW founders, raised a key question about women's liberation in her book *The Feminine Mystique*. “Who knows what women can be when they are finally free to become themselves?” (Friedan 1963, p. 378). Her critical review of women's roles as housewives helped citizens see how women were restricted in their ability to develop into full persons. Coalitions between the women's movement and the New Left, the anti–Vietnam War campaigns, the black liberation movement, and the ecological movement produced a variety of feminist theories and analyses, each of which explained liberation differently. Liberal feminism sought legal rights on a par with men's rights; socialist and Marxist feminism sought economic equity; radical feminism sought liberation and recognition for women-based theories, cultures, and sexualities; eco-feminism sought to explain how the subjugation of women is connected to the subjugation and abuse of nature; and postmodern feminism sought linguistic equities.

As the Second Wave of the women's movement progressed, pejorative nicknames like women's libber emerged as some social groups began to resist the changes. While there were feminists who wore the label libber or radical proudly, embracing the popular adage that “feminism is the radical notion that women are people,” others found that the labels hindered other types of political work. Feminists fought against the stereotype of themselves as man haters and humorless. While women as a group were oppressed, many also belonged to privileged groups: whites, elites, developed nations, majority religions, and heterosexual dyads. Since the term liberation could be understood as liberation from men or from slavery, other terms were employed to discourage these misunderstandings. Instead of using the term women's liberation, many political activists and scholars refer to this concept with the terms feminism or gender equity.

Groups within the feminist movement who focused on rights put their energies into legislation, gaining political office, protests, and litigation. Others were concerned with cultural transformations and focused on reframing language, what counted as the canon in art and literature,
everyday life activities, the division of labor in the household, and images of women presented in schools and the media.

“The personal is political” was a phrase that articulated the ways all women could be involved in this process of change, and personal choices were seen as manifestations of political commitments. The genuineness of a political commitment was indicated in the details of how one lived one’s life. Those who were vegetarian were expected not to wear leather shoes. Those who believed women were equal to men were expected to refer to adult females as “women,” not as “girls.” Hence a notion of political connection between individual actions and political beliefs was advocated, and this led to a form of “political correctness” in that one’s personal behavior was to match one’s ethical commitments. Progressive activists would point out such inconsistencies in each others’ actions in order to discourage patriarchal practices. Such actions examined and corrected speech practices to alert citizens to inconsistencies between political commitments and personal utterances. Calling adult women “girls” or referring to women as “chicks” could elicit public criticism. The Second Wave established inclusive speech practices for both genders that are now accepted in the society as a whole.

Affirmative action programs were put in place to recruit women and minorities into schools and the workplace, and watchdog agencies were created to be sure that such policies were followed. Sexism and racism were scrutinized, and citizens became aware that they needed to be careful about engaging in these types of behaviors. Some of these programs and the scrutiny associated with them have diminished with the rise of the New Right and its critiques of affirmative action, abortion policies, and other limits on corporate interests. The New Right resurrected the term political correctness to suggest that feminists and their allies had unduly politicized issues that were best left to individuals or corporations to work out as they thought best. Drawing from the ways in which politics has been treated as a negative term, the new use of political correctness permitted a quick negative label for social practices (especially related to affirmative action, protections for equal political and economic access for women and ethnic minorities, and inclusive language practices) that the political right wanted to eliminate from social policy.

Because rights in the United States are focused on limits to government action, U.S. politics has focused on how states have prevented women’s access to contraceptives and abortion as well as preventing corporations from discrimination in employment and educational opportunities on the basis of gender or sex. The New Right in the United States has developed an antibortion component to their political agenda with a “pro-life” argument based on the protection of what they call the unborn. This position builds on the general interests of the New Right in gender politics. Antifeminists have attempted to reduce women’s liberation to women’s individual opportunity and even to “bra burning” by making the claim that Second Wave feminists burned bras. However, the occurrence of this event cannot be found by those who study the movement even though it was reported in the media. Reducing a movement to “bra burning” was probably a confusion with the anti-Vietnam War movement that burned draft cards, an illegal activity that did serve as civil disobedience. While burning draft cards is illegal, there is no such law against burning bras; discussions about bra burning are designed to trivialize women’s liberation. The central issues of the Second Wave movement were equal access to education, employment opportunities, and health care.

Internationally, gender issues have included a struggle over women’s identities as wife and mother with a primary location in the modern private sector as opposed to women’s identities as political citizens with economic roles in modern societies that include but are not limited to their roles within the family. Because the world economy depends on women’s economic contributions to the economies of nations, the limitation of women to the private sector of the home has disappeared as an economic factor even though the issue remains alive as an emotional factor in some political ideologies or religious interpretations. These issues were debated at the 1995 UN Conference on Women in Beijing, China, where representatives from major religions, the political right and left, and other sectors discussed what is required to liberate women.

In an international context, the key issues for feminists remain women’s access to educational opportunities, including educational levels comparable to those offered to men, employment and pay opportunities that afford a living wage and are comparable to the pay men receive, and access to health care. In some nations women continue to struggle for equality with men in suing for divorce and custody of their children. Government policies vary on reproduction regulation, including abortion. In some nations abortion is limited to early stages or conditions that depend on the life of the mother. In others, such as China with its one-child policy, abortion can be encouraged and supported up to later stages of pregnancy. While some would reduce women’s liberation to access to reproductive health technologies, women’s liberation depends on access to general health care, education, and wages that will reduce women’s poverty and the devastation that comes when women are unable to provide for themselves, their families, and their children.

As the political climate developed in the 1980s and 1990s, feminists no longer had to contend with the prob-
lems of invisibility or of not being taken seriously. Nonetheless, while they were taken seriously in the 1990s, they were targeted by the New Right as a source of social ills. Internationally, a New Right, neoconservative feminism emerged that emphasized the role of women as wives and mothers. In the United States these activists are often part of the “pro-life” movement that has opposed abortion and worked to counter the effects of Roe v. Wade. They have argued that women did not need and would not benefit from the individual protection that could be granted through social and political rights that are the same as those granted to men. At the same time, among Western feminists, tighter alliances were built with the gay and lesbian movements, so issues of sex and reproduction remained important in the struggle over what counts as women’s liberation.

THE THIRD WAVE
In the 1990s postmodern analyses came to the foreground with a focus on the politics of language and culture and an emphasis on everyday political transformations as well as notions of difference. These shifts placed greater emphasis on culture and language as mechanisms for change at local levels. As the children of the Second Wave of feminism began to reach adulthood, they became activists with a new agenda that embraced the postmodern turn to language and cultural issues but also focused on mentoring, leadership, art, and new articulations of feminine and feminist identities. Rebecca Walker, the daughter of the Second Wave activist and novelist Alice Walker (b. 1944), is an example of a Third Wave activist. Building on Second Wave feminism, these activists and academics raise new questions such as that found in Leslie Heywood and Jennifer Drake’s Third Wave Agenda: “Which personal? And whose politics? How to think ‘sisterhood’ in terms of difference and hybridity?” (Heywood and Drake 1997, p. 23). Examinations of multiple identities, complex articulations of feminine and feminist, coalition politics, and everyday practices became even more important than party affiliations and legal reforms. Retaining a loyalty to womanist perspectives and multicultural understandings, feminists continued to argue that each woman must gain the opportunity to tell her own story and speak for herself.

As academic feminism moved from the Second Wave feminists, who had drawn on empirical evidence to substantiate gender bias, to Third Wave academics, who drew more from postmodern theoretical frameworks, linguistic playfulness became a form of politics. Third Wave feminists have focused on reinventing women’s identities, languages, and symbols while framing their own articulations of feminist politics. In this context women’s liberation means the freedom to select the context for political change, the ability to frame the issues in response to both contemporary and local contexts, and the means by which various surprising reversals, including linguistic turns, might liberate.

Women’s liberation is a part of the women’s movement, which includes access to education and political office; health care benefits, including reproductive health benefits; legal rights for women; employment access; protection from rape, domestic violence, and sexual harassment; access to professions and professional development; and protections from unwanted medical interventions and practices that put men in charge of women’s lives. The democratization of nation-states depends on women’s liberation because 50 percent of the population of a nation—women—cannot be denied equal participation and rights if a democracy is to emerge. Such denial undercuts democratization.

Women’s liberation has come to mean liberation from patriarchal practices. However, the ways liberation might take place and what practices count as patriarchal are matters for political debate, and women, like men, differ in their assessment of their own needs. While there are similarities in women’s situations, different contexts and values create different understandings of what women’s liberation requires and how it might best be achieved. These differences offer important political insights for social justice and the development of strong democratic societies.

Women’s Movement

The women’s movement has often been called one of the most important social movements of the twentieth century. Its most basic goals are to improve women’s social, economic, and political conditions by facilitating personal transformations, introducing new ideas to public discourse, and exerting pressure on policymakers. In addition to voting, it has been a key form of women’s political participation, joined only recently by greater numbers of women in political office. Beyond these basic features, however, there is considerable diversity among specific women’s movements around the world.

First, not all types of political engagement by women would be considered a women’s movement. As Karen Beckwith emphasizes, the term women’s movements refers to any kind of systematic organizing by women, including that of a nonfeminist nature (Beckwith 2000). Women’s movements are thus distinct from women in social movements, who are female participants in social movements that may or may not focus on gender issues. They are also a broader phenomenon that includes but is not equivalent to feminist movements, which engage women—and some men—through a more explicitly gendered lens that seeks to understand and overcome women’s subordination.

Second, women’s movements themselves vary enormously across countries and over time. They appear during different waves of feminism, originate in various kinds of other social movements, espouse a range of different issues of concern, and interact in numerous ways with global and regional trends. In addition, they are situated within a variety of social, economic, and political contexts that shape their emergence, development, and prospects for success. As such, many analysts are skeptical of universalizing claims about women’s mobilization. When studying “the women’s movement,” therefore, they seek to understand the diverse conditions under which women organize as women—rather than with men—to achieve social, economic, and political change.

Waves of Feminism

Although women’s movements are not synonymous with feminist movements, the two frequently overlap. As a result, one common starting point for analyzing women’s movements is to position them in relation to waves of feminism. Due to important differences in context, the timing and character of these waves vary significantly across countries. In the western world, the “first wave” is generally associated with the mobilization of women’s groups across many countries in the late nineteenth and early twentieth centuries. The main focus of these movements was to attain basic rights for women, including the right to vote, the right to employment, the right to receive equal pay, and the right to retain their own nationality upon marriage to men of other nationalities. Focused on equality, these campaigns largely sought to gain rights for women that were already guaranteed to men. However, in many cases these movements overlooked crucial issues of race and class, devoting most of their attention to rights for white and upper-class women.

The “second wave” of feminism, often dated in the West to the 1960s and 1970s, embraced a much wider range of theories and issues. Initially inspired by the need to dispel the “feminine mystique,” or the idea that women found their life’s fulfillment in being married and raising children, second-wave groups began to question women’s roles in the private sphere and to point to the social construction of gender roles. Drawing on ideas introduced by writers such as Simone de Beauvoir, they made a distinction between the terms sex and gender, using sex to refer to biological differences between male and female and gender to denote social differences between masculine and feminine. Although sex and gender were related, second-wave feminists emphasized that the relationship was imperfect, as men could be feminine and women could be masculine. Women’s groups developed these ideas in a number of different directions: Some stressed the universality of women’s oppression, some sought to revalue the “feminine,” and still others aimed to break down the distinction between the public and the private through slogans such as “the personal is political.” Despite this diversity, the shared feature of all these efforts was to focus on women as women, rather than as individuals who aspired to a male standard.

The feminist project of defining the terms women and women’s issues, however, was not without controversy. On the one hand, activists disagreed as to the coherence of “women” as a group. Many called attention to race- and class-based exclusions that were implicit in discourse on “universal” female oppression that in fact reflected the experiences of women from dominant racial and class groups. Others noted that accounts of the sexual division of labor, and especially women’s experiences as mothers, tended to assume that all women were heterosexual, thus overlooking—and marginalizing—the experiences of lesbians. On the other hand, feminists prioritized a wide range of women’s issues that implied distinct—and even conflicting—visions of the status quo and prescriptions

Eloise A. Baker
for change. Whereas some aimed to undermine patriarchy by promoting women's status in the public sphere, others sought to foster a "women's culture" by revaluing women's labor inside the home, raise awareness of women's experiences through consciousness-raising, and theorize patriarchy by pointing to the power that men exercised over women through violence and coercion.

The "third wave" is a more contested concept, existing in an uneasy relation to the term postfeminism. Both notions are generally taken to refer to ideas that emerged in the West in the 1990s and continue to develop through the present day. This wave is largely characterized by a focus on difference, both between women and men and among women themselves. At the same time, it aims to break down binary categories by emphasizing the fluid and relational aspects of identity and experience. As such, it questions traditional approaches to conceptualizing sex and gender by exploring intersections between race, class, and gender; uncovering the assumptions of heterosexuality that underpin analysis of women in relation to men; and probing the possibility that gender may cause sex rather than sex causing gender. In this sense, the third wave incorporates a number of ideas articulated by feminists of color, lesbian feminists, and postmodern feminists. However, because these theories stress the contradictions and multiplicities inherent in definitions of women and women's issues, they have paradoxical effects on women's movements: They help build coalitions with other movements for social justice, but also undermine the prospects for mobilizing by women as women for social, economic, and political change.

ORIGINS OF WOMEN’S MOVEMENTS

Many scholars draw on the wave analogy to identify major shifts in feminist theorizing and their relation to concentrated periods of mobilization by women's groups. This approach has its critics, however, who point out that women are active politically between waves and are not always inspired initially by feminist concerns. Indeed, despite the widespread belief that women's movements emerge in cycles as women become more educated and politically informed, evidence from around the world suggests that women's movements often have their origins in various other kinds of social movements. In these cases, women gain a shared sense of gender oppression through discrimination they experience in the course of their participation in other campaigns for social justice. These include movements for civil rights, revolution, nationalism, independence, and human rights. Similar consciousness-raising also occurs in authoritarian regimes, where the creation of state-led women's organizations aims to control women's political activity but sometimes provides an official platform for women's organizing. Many women's movements nonetheless hesitate to label themselves "feminist" on the grounds that the term has various negative associations as "bourgeois," "Western," "forced emancipation," and even "man-hating." Further, few movements succeed at incorporating all women due to differences among women that remain important, including nationality, race, class, religion, region, language, and sexual orientation.

ISSUES OF WOMEN’S MOVEMENTS

Given their distinct origins and relations to waves of feminism, women's movements around the world focus variously on a wide range of issues. These concerns fall into six broad categories: women's legal rights, violence against women, reproductive choice, sexual freedom, employment opportunities, and discrimination, and women's political participation and representation. Legal rights include such issues as rights in marriage, the right to divorce, and the right to own and inherit property. Violence against women refers to practices such as rape, domestic abuse, female genital cutting, sexual slavery, and sex trafficking. Reproductive choice encompasses access to contraception, the right to abortion, and the right to not be subjected to forced sterilization. Sexual freedom involves the right to express one's own sexuality and claims for the same privileges conferred on heterosexual couples. Employment opportunities and discrimination include rights to equal pay, access to all jobs, provision of maternity leave, and freedom from sexual harassment. Women's political participation and representation, finally, comprise the rights to vote, join political parties, participate in civil society, and run for political office. Individual movements rarely cover all these issues, and specific movements address particular issues in a variety of different ways. In addition, some groups mobilize to preserve rather than undermine women's traditional status as mothers and inside the home.

GLOBAL AND REGIONAL WOMEN’S MOVEMENTS

Despite their emergence and development in specific contexts around the world, women's movements inform and reflect broader global and regional trends. Women's organizing has always had an international dimension, reaching back more than 100 years to the early suffrage campaigns and activism for world peace. In the last thirty years, however, women's movement activism has grown exponentially in relation to developments beyond national borders. At the global level, international conferences have placed new issues on national political agendas and facilitated networking among women's groups around the world, even as they have been marked in some
instances by sharp conflicts among women in developed and developing nations. At the regional level, transnational organizing has become increasingly important as a means for spreading new ideas across national borders, fostering policy diffusion and solidarity among politically marginalized groups. Despite their long history, women’s movements are thus constantly being reborn, reinventing themselves, and taking on new forms in order to politicize women’s concerns, however these are identified and defined.

WOMEN’S STUDIES
Women’s studies is an interdisciplinary academic field that concentrates on the experiences and aspirations of women. Although women’s studies departments and programs in the United States and around the world are reflective of their locations within educational institutions and their larger social context, a common thread is the claim that women’s experiences have been underrepresented or misrepresented in more traditional academic disciplines that claim to capture the human experience. This has been found by some critics to be the case in traditional disciplines that purport to speak about human nature but consider only the social location of men or take men as the universal subject, casting women as either substitute or inferior men.

WOMEN’S STUDIES AS CRITIQUE AND CORRECTIVE
Arguing that women are human too and that the academic is also political, women’s studies is founded on critical terrain, offering critiques of traditional disciplines and correctives to their representations or exclusions of women. Thus, a women’s studies program may offer courses in education, literature, history, political science, philosophy, psychology, ethnic studies, biology, medicine, religious studies, and international relations, among other fields, centralizing women and the theoretical frameworks of feminism within each of those fields. Further, the misrepresentation of women’s experiences in academic disciplines is thought by some to reflect a generalized societal devaluation of women’s experience and social roles and thus to be part of the oppression of women. In this way the purpose of women’s studies is shaped by its relationship with women’s movements inside and outside the academy. The field has developed around the idea that the personal is political, meaning that gender identity and the subjectivities of individuals are shaped through the political structures of a gendered social system.

In these ways the field of women’s studies is a critique and a corrective as well as a self-reflexive and politically engaged discipline that functions with a commitment to social transformation within education and the wider society in which it exists. Since their inception women’s studies programs have operated from the often contradictory position of educating for social change and existing within traditional academic institutions that tend to favor neutral and disinterested knowledge production.

EARLY COURSES AND PROGRAMS
The first women’s studies courses were offered in the United States in 1965 at the New Orleans Free School, the University of Chicago, Barnard College, Spelman College, and the Free University of Seattle. The earliest women’s studies program was established in 1970 at San Diego State University, and the Women’s Resource and Research Center was established at Spelman in 1981. Influenced by the civil rights, women’s, and New Left movements and the inception of African American,
American, and ethnic studies, early women's studies courses were guided by a vision of a world free from sexism, racism, class bias, ageism, and heterosexual bias.

The scope of the field has expanded continuously, increasing from 150 women's studies programs in the United States in the period 1970–1975 and three cross-disciplinary journals in 1972 to the growing number of courses, programs, departments, academic conferences, and journals of the first decade of the twenty-first century. In 2006 there were over seven hundred degree-granting women's studies departments in the United States with approximately seventeen doctoral programs, including the Africana Women's Studies program at Clark Atlanta, the Graduate Certificate Program at Howard University, and the earliest doctoral program at Emory University; more than two hundred fifty women's departments in sixty countries worldwide, with approximately twenty-five doctoral programs; and over forty scholarly journals and dozens of annual national and international conferences. The U.S. National Women's Studies Association (NWSA) was founded in 1977, and Women's Worlds: International Interdisciplinary Congress on Women was founded in 1981 with conferences held since that time in locations ranging from Haifa, Israel, to Seoul, South Korea.

METHODOLOGY AND STRATEGIES
The primary methodological approach of women's studies is derived from feminist analysis, a complex field of study that questions the foundations of traditional male-centered knowledge. Feminists have interrogated the masculine—also known as the patriarchal, androcentric, and phallocentric—biases and exclusions of prevailing social relations, institutions, and political structures to understand why women consistently experience gender-based oppressions that are manifested differently in accordance with the context. From home, to schools, to the workplace, to neighborhood streets, to war zones feminists have demonstrated the ways in which women, by virtue of being female, are barred disproportionately and systemically from the privileges enjoyed by men. At the same time feminist analysis documents women's political agency and resistance to oppressive circumstances. This has been particularly true of black feminist traditions.

To rectify structurally derived inequalities between men and women, one set of approaches feminists have offered consists of strategies to oppose existing masculine structures. Feminist oppositional solutions have taken a number of forms, from proposing equity in the workplace, government, and home to more profoundly transformative solutions of challenging masculinist epistemologies with feminist ways of knowing. Whereas man has dominated the social and human sciences, feminists have proposed woman as a replacement, a supplement, or the basis for structural transformation.

A number of concerns about the transformative potential of feminist oppositional strategies have been articulated within feminist debates. Proposing woman as an oppositional category immediately raises the question of whether gender is the primary identification of all women everywhere, casting doubt on the core of much of feminist politics. Racialized women, lesbians, disabled women, working-class and poor women, and women outside North America and Western Europe have been the most insistent voices against homogenizing women into hegemonic categories, thus contributing to the plurality of feminist analyses.

The long tradition of black feminist thought, for instance, has reconceptualized feminism by demanding attention to race, to diaspora communities, and to the construction of womanhood outside the United States. Debates about difference, or multipositionality, within women's studies programs continue, revolving around the ways in which race, class, nation, ability, age, and other social locations modify gender. Not only was the notion of woman challenged, the entire notion of a core focus or single identity was challenged by debates that demanded intersectional, plural, and culturally attentive approaches to feminism that are simultaneously antisexist and antiracist. For women's studies programs that primarily have focused on the experiences of white women the challenge is to integrate a racial analysis; for programs within historically black colleges and universities the challenge is to integrate a gender analysis into already established racial analyses.

DEBATES WITHIN WOMEN’S STUDIES
Starting from their initial questioning of man as the legitimate grounds of knowing, feminism and women's studies debate the proper subjects and objects of the field. In this sense feminist and women's studies debates are both reflective of and a challenge to broader debates within the social sciences about conventional criteria of knowledge production, disciplinary configurations of relevance, verifiability and falsifiability, the separation of subject from object, and the criteria of objectivity and universality as necessary features of legitimate knowledge production. With the “crisis of reason” comes the instability of feminist claims to know, and feminism is both oppositional to and implicated in conventional epistemological discourses. In fact, the very immersion of feminism in patriarchal practices is seen as a factor in the critical effectiveness of feminism and thus the transformative potential of the field of women's studies.
These debates manifest themselves in a variety of ways in women's studies programs. Pedagogically, the field of women's studies has attempted to create inclusive, non-hierarchical, and open learning environments that do not privilege hegemonic voices or experiences. In this regard peer facilitation, experiential knowledge, and self-reflection are emphasized in many women's studies programs. Epistemologically, women's studies programs offer feminist theory and methodology courses in interdisciplinary and politically engaged knowledge production. This means that women's studies programs provide courses that centralize women's experiences as well as methods of reading the social through feminist theory. Normatively, women's studies courses tend to highlight the value biases of feminist theory and demonstrate the hidden values of knowledge that is said to be neutral and disinterested. Institutionally, women's studies programs are often in an uneasy alliance with academia, on the one hand attempting to offer transformative curricula and on the other hand finding it necessary to offer courses and programs that are recognizably legitimate in comparison with other liberal arts degree programs. Additionally, women's studies departments often seek models of departmental governance that maintain some of the ideals of feminist organizing while operating within the larger institutional framework. Finally, the field of women's studies continues to nurture its relationship with women's movements and community activism beyond the academy.

Beyond women's studies programs and departments, feminist analysis has found its way into many traditional disciplines and departmental appointments. In light of the mainstreaming of feminist analysis, the question arises whether women's studies as an autonomous field has outlived its utility in the academy. At the same time there are qualitative differences between working as a feminist scholar within a discipline that does not centralize the project of academic and social transformation and working within an interdisciplinary women's studies department that is intended to transform the entire educational experience from the classroom to departmental governance.

As women's studies programs have increased their legitimacy within the academy, acquired departmental status, increased their number of tenure-track appointments, and developed doctoral programs, the negotiations about remaining transformational and autonomous have continued. In that context the field of women's studies is dynamic, worldly, and continuously engaged with the central epistemological and normative debates that animate much of the social sciences.

WOODSTOCK

Although the Woodstock Music and Arts Festival is a celebrated symbol of the “hippie” counterculture, it did not initiate the counterculture, nor did it mark its end. Nevertheless, Woodstock is a useful reference point for discussions of this significant social phenomenon. By 1969, the “hippie” movement had emerged as a group of primarily young people, who not only were opposed to
the Vietnam War but also wore distinctive and colorful clothing, engaged in illegal drug use, and enjoyed rock and roll music.

In early 1969, business associates John Roberts and Joel Rosenman met record executive Artie Kornfield and festival promoter Michael Lang, and the four decided to produce the largest music festival to date. Although not fully immersed in the counterculture, they sought to produce a festival that would appeal to that group. To promote the festival they formed Woodstock Ventures, named after the town in Ulster County, New York, where Bob Dylan lived. Woodstock Ventures advertised the festival in the alternative and college media, hired a crew to assist with production, and booked the most significant bands of that era. Their most difficult concern was finding a site to hold a large, three-day music and art festival, which would also allow attendees to camp. Woodstock Ventures eventually found a site in Sullivan County, New York. They leased land from a local dairy farmer named Max Yasgur. Although Sullivan County residents expressed trepidation about the concert and especially the influx of “hippies,” Yasgur resisted this pressure and allowed the festival to occur.

Woodstock started on Friday, August 15, 1969, and on that day, approximately 400,000 (some estimated closer to one million) people, many without tickets, arrived at the festival gate. Fans waited hours in line, and when they entered, it was clear that they were not prepared for three days of camping. To make matters worse, it had rained considerably during the weekend, soaking the festival grounds. The promoters also did not adequately prepare for the throngs of attendees, and eventually they agreed to waive admissions fees.

Woodstock is the quintessential symbol for the “hippie” counterculture. Illegal drug use was extensive and open. While most of the fans maintained control, a small percentage of them overindulged, though there was also a “freak-out tent” to calm them down. Woodstock included a self-contained market, in which fans sold food, artwork, jewelry, and clothing to one another. The artists, promoters, and fans were more concerned about music and art than about politics, but the undercurrent of progressive activism was inescapable. The musicians and fans expressed support for social justice and intense opposition to the Vietnam War.

Woodstock attracted considerable media attention, which brought the “hippie” counterculture into the mainstream, and, as a result, the festival became part of the American cultural imagination. Although the festival was only one of many crucial events during a time of social and cultural upheaval, intellectuals, the press, popular entertainment, and the advertising industry have made Woodstock into the symbol of the cultural and political ideals of the late 1960s. Supporters of the social changes brought about by the 1960s cite the ability of the festival to overcome tremendous obstacles as an example of the success of the “hippie” subculture and progressive politics. Conversely, opponents of these changes deride Woodstock as an example of the chaos and lawlessness the 1960s wrought on American society.

Although in the early 1970s many experts predicted the end of the “hippie” movement, the spirit of Woodstock has not disappeared from the American cultural scene. Throughout the 1970s, 1980s, and early 1990s, the Grateful Dead, which had been at the forefront of the “hippie” movement and performed at Woodstock, played thousands of shows throughout the United States. A new generation of fans, known as Deadheads, many of whom were not born when Woodstock occurred, followed the band to different cities. Like Woodstock, Grateful Dead concerts featured illegal drug use, expression of progressive views, and vibrant economic activity. This subculture was so significant that University of North Carolina, Greensboro, sociologist Rebecca Adams set out to study Deadheads by attending shows and conducting field research on the fans (Adams 1998). During the 1990s a second generation of musicians and fans maintained the Woodstock spirit. So-called jam bands, such as Phish, have developed their own followings, especially after the 1995 death of Grateful Dead band-leader and “hippie” icon Jerry Garcia. Since 2002, the Bonnaroo Music and Arts Festival has occurred every June in Manchester, Tennessee. Although this festival only attracts 90,000 to 100,000 people and is generally well organized, it is strikingly similar to Woodstock. An eclectic selection of bands entertains fans; there is widespread and open illegal drug use; progressive political views abound; and people sell food, art, and clothing.

WORK

It may seem that everyone knows what work means—most people have engaged in activities that they call work, and they know that institutions and social structures are
sustained through the work of large numbers of individuals in society. Yet, a closer examination reveals that the concept of work has a long and contested history. Peter David Anthony, for example, characterizes work as anything that gives people “moral responsibility” and “spiritual significance.” He writes that “if life has any meaning, work has meaning because life is work” (1980, p. 419). Along the same lines, Sean Sayers notes that “the experience of being without a job is profoundly demoralizing and unfurling” (1988, p. 731). In contrast, Herbert Applebaum argues that “work in the modern world is purely instrumental. It is a mere means to gain a living, not an activity of value in itself, not a means of self-expression” (1992, p. 573). Paul Thompson (1983) characterizes work as a loss of autonomy and an experience of being confined by the scheduling and disciplining of others. As Nona Glazer summarizes, work is “a problematic concept” (1993, p. 33).

Common to the various debates on the meaning of work, however, is the recognition that in the contemporary social and economic system, work has an economic and moral function. As Arlene Kaplan Daniels notes, in modern industrialized society, “the most common understanding of the essential characteristic of work is that it is something for which we get paid” (1987, p. 403). In addition, the recognition of an activity as work gives it a “moral force and dignity”: “To work and earn money is also to gain status as an adult” (p. 404).

Many of the ways in which we think about work in relation to pay and value have been influenced by the writings of Karl Marx (1818–1883). Marx noted that the process of exchange makes all the different types of labor homogeneous; this homogeneous labor, which produces commodities, is called abstract labor. Value is measured in terms of abstract labor, which in turn is measured in terms of the time necessary to produce a commodity vis-à-vis another commodity (Bottomore 1991a, p. 565). In this way, Marx described value as “not something intrinsic to a single commodity apart from its exchange from another” (Bottomore 1991a, p. 566). Marx constructs value as a social relation rather than a description of a thing (Rubin 1972, p. 70). Under capitalism, labor—or work—itself becomes a commodity that is bought and sold. One of the central ways that we organize our understanding of work is in terms of the jobs people do. Jobs are classified into sectors, such as agricultural, industrial, manufacturing, managerial, and service, according to the main activities involved. Around the world, jobs are deeply stratified by gender. For example, women tend to predominate in agricultural employment in Asia, sub-Saharan Africa, the Middle East, and North Africa. Women in most parts of the world hold many of the jobs in the service sector, such as community, social, and personal services, whereas men dominate in the business and financial sectors (Elder and Schmidt 2004).

Not all labor, or work, is valued equivalently. Work done by engineers, financiers, and managers is well paid, while the service jobs in which many women, people of color, and recent migrants are employed are precarious and poorly paid. According to the International Labour Organization (ILO), 1.39 billion people (almost 50 percent of the world’s workers) do paid work but earn less than two dollars per day. These people form the working poor, who are employed yet simultaneously live below the poverty line (ILO 2004).

Many scholars have focused their analyses on how work is deeply stratified in terms of gender. Peta Tancred notes that it is often assumed that “women are born with certain ‘natural’ skills which require neither talent nor training, and which are merely part of their ‘natural,’ feminine behaviour” (1995, p. 17). Jane Aronson and Sheila Neyesmith document the experiences of home-care workers who do work that is similar to that which would otherwise have been assumed by female relatives. Although home-care workers are paid, their work is accorded little status and assumed to require little skill (Aronson and Neyesmith 1996, p. 61).

Feminist theorists also provide vivid illustrations of the ways in which individuals are expected to re-create particular versions of masculinity and femininity as part of their jobs. Lisa Adkins, for example, discusses the jobs of catering assistants within a leisure park, where women are required to have the “right” appearance to be employed. This “right” appearance includes being “attractive and looking fresh” and not looking “weird” or “too butchy” (Adkins 1995, pp. 105–106). Adkins’s study provides an illustration of the ways in which occupations are segregated not only by sex (i.e., biological femaleness or maleness) but more importantly by gender (i.e., appropriate manifestations of masculinity and femininity).

Jobs, and the organizations within which they are situated, do not just require individuals to conform to stereotypical notions of femininity and masculinity. As Jennifer Pierce notes, gendered structures shape “workers’ practices at the same time that … workers participate—wittingly or not—in the reproduction of gender relations” (1995, pp. 2–3). Gender is a continual process, being actively created and resisted within organizational structures. The ways in which women and men both reproduce and re-create a variety of gender norms through their jobs is illuminated in Elaine Hall’s analysis of interactions between table servers and customers. Hall demonstrates the ways in which expectations of behavior conforming to stereotypical notions of masculinity and femininity are not universally held, but rather are contextually developed. For example, both female and male table servers
think that the public expects waitresses to be more friendly than waiters and “cross-sex interactions to be more friendly than same-sex interactions” (Hall 1993, p. 460). Female customers, however, are seen only by the waiters, and not by waitresses, to be friendly. Friendliness is, in this case, not a component of femininity across contexts, but rather a gendered process developed within the particular work role assigned to waitresses (termed by Hall a service script) (1993, p. 461).

In addition to the gendered nature of work, only certain activities are labeled as work in the first place, depending on the social context. An activity such as sewing a shirt can be paid work, unpaid work, or leisure, depending on the context. This raises the questions of how certain activities get labeled as work and how some are deemed worthy of remuneration. Feminist theorists have noted that the strong economic orientation in conventional understandings of work fails to recognize much of the “work” that women do in our societies. Domestic chores and childcare are seldom recognized as work, even though they require more effort, commitment, and skill than many paid jobs. In fact, a lot of work is difficult to classify in terms of payment. Marjorie DeVault (1991) describes the work that goes into feeding a family, which involves not only cooking but also planning, provisioning, and being attentive to family members’ nutritional needs and individual tastes. Many of these activities are not only unpaid, they cannot be paid for. For example, if one were to make a detailed list of the activities that are involved in finding a place to live in a new city, one would find that many of the activities (such as figuring out where like-minded people live; balancing such factors as the size, brightness, and proximity of the apartment; and reconciling the needs of various family members) cannot be done by others, even for pay. These activities require emotion work (Daniels 1987).

As Deanne Messias and colleagues argue, “attempts to define work in terms of economic activity are met with the problems of having to determine where noneconomic housework ends and economic activity begins” (1997, p. 307). Given that women more often than men assume primary responsibility for family work (Pierce 1995) and that women are significantly more likely to be employed in jobs requiring emotion work (Wharton 1993), much of women’s work is not only unpaid, but also cannot be paid for. Writers have called these tasks tailoring work and note that it is such invisible work that sustains many of our social structures. Daniels, for example, argues that “the normative expectation in every industrialized society is that women will coordinate public and purchased services with the private requirements of their families [and] … this tailoring is … part of the invisible work in social life” (1987, p. 405). Glazer provides illustrations of the tailoring work that women do through her analysis of the growth of self-service and self-care in the American retail and health-care industries. Self-service in shopping, for example, translates into considerable work for the customer. This work, done by women, involves gaining knowledge about goods, locating and evaluating items, and transporting goods to the home. The tailoring work involved in shopping is constructed as leisure (Glazer 1993, pp. 49–102). In a similar way, cost-cutting measures in health care involve a “work transfer” where women learn and do high-technology health care at home, which includes providing food, changing linen, bathing, toiletting, keeping detailed records, and administering medication. This care is treated as “routine housekeeping” rather than being recognized as skilled work integral to the U.S. health-care system (Glazer 1993, p. 179).

The discussion above illustrates the political nature of the concept of work and the ways in which different definitions of work signify gender, race, and class hierarchies within society. It can be seen that only certain activities are labeled as work, depending on the social context. William Ronco and Lisa Peattie, for example, ask what distinguishes work from a hobby and reveal the fuzziness of these categories. They conclude that “the distinction between ‘work’ and ‘hobby’ is thus not inherent in the activity; it lies in the social context in which the activity is carried out” (1983, pp. 13–18). The consequence of the social labeling of only certain activities as work is that these activities hold higher financial and normative status in contemporary society. Given the importance of unpaid, family, and emotion work, conventional definitions of work need to be constantly challenged.

WORK AND WOMEN

The term work, generally implying some sort of activity or achievements, acquired specific connotations due to the development of capitalist productive relations (Williams 1976), particularly since the Industrial Revolution in the late eighteenth and early nineteenth centuries in Britain. Under capitalism it is the payment of wages that makes clear the distinction between work and nonwork. The notion of work came to be associated with some sort of paid employment, so that time spent outside waged employment is not considered “work” but leisure time. For example, taking care of one’s own household and children—a job typically done by women—is usually considered nonwork because it is a non-wage-generating activity. In fact, the dichotomy of work versus nonwork can be best understood if we look at how women’s work has evolved through centuries in our society.

Though a single basis of comparison cannot be regarded as absolute in comparing historically what constitutes women’s work across different cultures, studies have demonstrated that historically women in many so-called developed and developing countries have actively taken part in forms of work that are generally regarded as non-productive or non-income-generating. For example, women in Asia, Africa, and Latin and North America engaged in a wide variety of jobs (e.g., raising livestock, processing food, fetching water and fuel, sewing, selling homemade pottery, child rearing and housekeeping) that may not have always conformed to the clear-cut distinction of work and nonwork produced by the discourses of capitalism (Kessler-Harris 2003). Although in the gendered division of labor women generally had the bulk of domestic work, this was considered vital to the survival of the family and the society. In the wake of capitalist economy, while women continued to engage in various subsistence crafts or family labor systems, the emergence of a male-dominated waged workforce diminished women’s visible role as productive workers. Women’s housework gained a pejorative connotation and was seen as segregated from the public (i.e., male) capitalist economy. As many of women’s traditional tasks (e.g., cloth manufacturing and spinning) became mechanized and production sites moved to factories, women’s work increasingly became coterminous with nonproduction that cannot be evaluated in monetary terms. Women who did enter the wage labor market because of family responsibilities were either assembling goods at home for subcontractors or working in factory jobs that were considered low status and attributed less value in relation to work done by men.

Thus according to Deborah Simonton (1998), the advent of capitalism and industrialization resulted in creating a distinction between the public (men’s) world and the private (women’s) world. Household work came to be exclusively a women’s activity, and the private world of home the ideal place for women. Women came to be identified more as mothers or caregivers and not as economic contributors to the family. As Elisabeth Prügl and Eileen Boris (1996) note, women, being identified with nurturing and caring, were separated from waged workers, and men
were considered the ideal waged workers and main breadwinners of their families. This role of women in society gained wider life even outside Europe, in many countries of Asia and Africa because of British colonization. However, this social role had different implications for middle-class and working-class women, and was gendered and racialized. For example, for women of the rising bourgeoisie in Victorian and Edwardian England, working outside the home was not considered “respectable,” and home was considered a woman’s proper place. However, working-class women were forced to work for financial reasons, although mainly as seamstresses, spinners, weavers, or domestic servants—jobs that are traditionally considered women’s work. These jobs were perceived as less skilled and inferior to men’s work and were paid less as well. Vis-à-vis class, the public/private divide had a racial dimension as well. For example, in the late nineteenth century, many African American women migrants who settled in the United States had no other option but to work as domestic servants in burgeoning urban middle-class families. Being racially excluded from most occupations, these women had to go out of their homes to earn a living for their families.

A major change in women’s role in society in the United States, Britain, and continental Europe came with the two world wars (1914–1918 and 1939–1945). At the outset of each war, as men left their jobs to enlist, the supply of workers declined, resulting in labor shortages. The crisis of war unsettled the prescribed and dominant gender and class codes, and this, compounded by economic pressures, made possible the entry of women into the public workplace.

Women started entering into jobs that were previously considered men’s domain, not only in manufacturing and agriculture, but also in banks and offices. Professions and careers also opened up in academia, medicine, law, and engineering. As women demonstrated their abilities to do skilled and highly mechanized work, they cast doubt on the dominant assumptions about women’s physical abilities and social role. New work opportunities instilled in women a sense of confidence and individualism so that domestic work was no more the ultimate goal in their lives. For a significant number of women, paid work outside the home came to represent economic and social mobility, and they were ready to balance work and home without giving up one or the other.

Deborah Simonton (1998) notes that in spite of the significant achievements made in the workplace in the post–World War II era, attitudes toward women’s roles at work and home have continued to be patriarchal and gendered. Household work and child rearing are still considered to be women’s major role, and women’s paid work is mostly seen as neglect of home and family. Marriage and the arrival of children thus mark an end to many women’s prospering careers in countries around the world. At the same time, certain jobs such as nursing and teaching are stereotyped as “women’s jobs” because they are assumed to be closely related to women’s “natural” caring and mothering roles; predictably, these jobs do not enjoy the same high social status as other official or clerical jobs belonging to the domain of men. Coupled with this, women in the workplace are expected to be polite, docile, apolitical, hardworking, and contented with a lower wage. Women are seen as casual or temporary workers, a reserve army of labor to be drawn on when needed and sent back when not required.

Economic restructuring and globalization since the 1980s have made women’s positions at home and in the labor market more gendered and unequal. As pointed out by Prügl and Boris (1996), women’s unpaid work at home has increased, as they need to compensate for care that was previously provided by the state. At work, because of the limited options in the formal sectors that consist of regulated, organized economies and protected workers, more and more women are forced to take up jobs in the informal sectors, where jobs are unregulated, part-time, low-paid, with no benefits or social protection and highly contingent in nature. Women’s share of informal sector employment thus remains high in many countries, through their involvement in self-employment, subcontracting production, family enterprises, and home-based labor. While these jobs contribute not only to families’ survival but to national income as well, they often go unrecognized or are considered peripheral and a mere extension of household work. For instance, women carpet weavers in Turkey or home-based garment sewers in Bangladesh who sew sweatshirts at home for multinationals are hardly recognized as “workers,” although their work provides important bases for national economic development.
